DESCRIPTORS	Academic Achievement; Accountability; Counselor Training; *Delivery Systems; Elementary Secondary Education; Ethics; Evaluation; Intervention; Prevention; *Professional Services; Professional Training; *School Psychologists; *School Psychology; Supervision; Theory Practice Relationship

ABSTRACT

The emphasis of school psychology on prevention, early intervention, assessment, collaboration, and problem solving requires counselors to have a tremendous range of evidence-based knowledge. This publication, divided into two volumes, is designed to provide a comprehensive reference for school psychologists on contemporary research and perspectives related to quality professional services. The information emphasizes a problem-solving approach to professional practice to improve student performance and enhance educational success in a demonstrable manner. The two volumes are divided into four parts with chapters clustered around the concepts of professional focus, improving student performance, assessment domains and special populations, and appendixes with practical reference materials. The chapters in Part 1 are related to the enhancement of professional services and the topics range from revisiting the shifting paradigm in school psychology to the standard topics on ethics, supervision, and accountability. Part 2 contains topics on interventions to improve student academic and behavioral performance. Part 3 considers assessment domains and special populations. Part 4 provides a set of appendices for reference which include standards, a listing of training programs across the country, and a full listing of National Association of School Psychologists position statements, training standards, and ethics. (Contains 48 tables, 101 figures, 4 appendixes, and over 900 references.) (JDM)

Preface

Best Practices in School Psychology IV, like the three preceding editions published by the National Association of School Psychologists (NASP), is designed to provide a comprehensive reference for school psychologists with contemporary research and perspectives related to quality professional services. The fourth edition maintains a theme that began in the third edition and is reflected in most of the chapters—emphasizing a problem-solving approach to professional practice.

A problem-solving orientation is distinguished by its purpose: to improve student performance and enhance educational success in a demonstrable manner. Problem solving is a systematic process that includes the assessment of children and their environments, identification of needs, development and implementation of supports to meet needs, and the monitoring and evaluation of outcomes. This orientation permits any theoretical approach in the design of interventions, but uses improved student performance and educational functioning as a criterion for measuring success. This commitment to improving students' performance and well-being is in harmony with NASP's mission of serving the mental health and educational interest of all children and youth.

As an aid to the reader the book is divided into four parts with chapters clustered around identified concepts.

Part I establishes a professional focus. Chapters in this section are related to enhancing professional services with topics ranging from revisiting the shifting paradigm in school psychology to mainstay themes within a profession such as ethics, supervision, accountability, legal issues, professional development, and maintaining professional effectiveness. These chapters present content that potentially influences all other professional services.

Part II presents a focus on improving student performance. Such a focus relies on understanding the design, implementation, and evaluation of interventions, in addition to mastery of a variety of topics associated with improving student academic and behavioral performance.

Part III considers assessment domains and special populations. Assessment is viewed very broadly, and the included chapters deal more conceptually with the issues rather than providing a specific guideline for action.

Part IV provides a set of appendices that will be useful professional reference including standards, a listing of training programs across the country, as well as a full listing of NASP position statements, training standards, and ethics.

Also as an aid to the reader, most chapters follow a common framework of headings. Each chapter, in addition to a list of citations from the professional literature, includes an annotated bibliography with up to five additional readings to provide more detail for those who wish an in-depth study.

We hope this organizational structure and the content of this publication will assist the profession in advancing the quality of services to educational systems, students, parents, and families. This is the intent and spirit of this publication.

The *Best Practices* series has been developed as an aid to the practitioner school psychologist who daily faces a multitude of situations and challenges. It is meant as a resource to provide a framework to deal with these situations and challenges within the context of our nation's schools. It is now, we understand, also used in many school psychology training programs to assist in the education of future professionals, though it is important to again reiterate that each chapter was written with the informed practitioner as the audience.

It is through our individual efforts that the profession collectively advances, and we hope this resource will be useful in that journey.

Acknowledgments

There have been numerous people involved in conceptualizing, planning, processing, and publishing *Best Practices in School Psychology IV*, and we would like to take this opportunity to acknowledge their invaluable contributions.

First, effusive thanks and acknowledgements go to the cadre of reviewers who read draft chapters, provided valued feedback to authors, and shared their perspectives of the varied topics. An earnest attempt was made to have each chapter reviewed by at least three practitioners and, in many cases, one university trainer. Once reviews (reviewers were provided a format for feedback) were received they were forwarded to the author along with copies of reviewer marginal notations and editor comments. It was a time-consuming process for the reviewers, and many authors' final manuscript substantially benefited from reviewer efforts. Reviewers who substantially contributed to this book include:

Ruth Adams, NJ
Carolyn Allen, SC
Amy Apthorpe Piper, NY
Sally A. Baas, MN
Thomas Barry, RI
Phillip Bowser, OR
John D. Boyle, IA
Alan Brue, TX
Mei Mei Burr, OH
Andrea Canter, MN
Servio Carroll, WY

We also need to thank our *Best Practices in School Psychology IV* Advisory Panel who was available to consult on thorny issues, political minefields, professional orientation, and any other challenges that could have potentially delayed the quality and timeliness of this publication. The Advisory Panel included Bruce Bracken, Jeff Braden, Andrea Canter, Deborah Crockett, Frank Gresham, Patti Harrison, Ruben Lopez, Leslie Paige, Dan Reschly, Susan Sheridan, and Cathy Telzrow. There were occasions we would create problems just for an excuse to communicate with such a talented and professionally active group.

With more than 100 chapters in some stage of preparation (author contact, submission of first draft, identification of reviewers, draft sent to four reviewers, tracking and assembling reviews, providing initial feedback to author, receiving final or second draft from author, copyediting the final draft, returning copyedited chapter to author for approval and/or changes, receiving author feedback on copyedited version, setting chapter in publishable chapter format, and providing publishable chapter format to author for final approval) you can imagine the considerable logistical challenge to track the stage of each chapter. Over the more than three-year process of completing this project some outstanding Miami University graduate students in school psychology have been of invaluable assistance. The manner in which they good humouredly and most competently juggled their studies, their field placements, and their *Best Practices* responsibilities certainly bodes well for this profession's future.

Mary Shinn was primarily responsible for setting up the tracking database and assiduously sending reminder emails and telephone messages to tardy reviewers and authors. Her grasp of the overall project made timely completion possible, and her two years of graduate coursework fortunately coincided with the beginning of this project (and her previous two years of Peace Corps volunteering and four years of New York city teaching did not hinder her, either). A more quietly competent person would be hard to find. Internship year beckoned for Mary, and it was our good fortune to have her work completed by an equally competent Mandy Grantz. Mandy effectively brought all the loose ends together to assure timely completion and anticipated all varieties of potential problems with a gifted prescience. Over the considerable development period of this book other school psychology students were involved in some aspects of communication or production. We thank them for their efforts. They include Lora LeMay, Kristine Joaquin, and Leslie Toleski.

Our appreciation is extended to the NASP Publications Board and particularly to the Board's liaison to this project, Leslie Paige. As usual, one can always rely on the members of the staff at the National Association of School Psychologists. Marilyn Brazier cleared potential bureaucratic barriers to ensure easy traversing, Rosemary O'Donnell continued to provide the "other duties as assigned" ombudsman role so common in school psychology job descriptions, and Susan Gorin was terrifically facilitative by providing continuing support and easy availability of a "thumbs up" when needed.

Linda Morgan from the NASP staff deserves credit for arranging the details associated with the production of this book and for finding the excellent professionals who did the copyediting, were responsible for the publishing, and developed the cover.

The copyeditor, Mike Schwartz, was really more than a copyeditor. He also contributed substantive comments and perspectives as well as the expected assurances that references were cited properly, tenses agreed, and tables aligned. He was a real talent who added continuity and cohesiveness to this project. Our frequent e-mails and phone communications will be missed. When Mike completed his copyediting Carol Levie most ably assembled the conglomeration of chapters into a coherent desktop form and creatively improved tables and lists, doing digital magic. We thank Mike and Carol.

Most if not all of the authors receive kudos for good-naturedly adapting to the conventions of an entirely electronically assembled book. All chapters were copyedited and processed electronically. It was the first such experience for us as editors and most of the authors who have grown up with paper copies and the arcane copyediting marks scribbled on manuscripts. We understood the challenges of adjusting to this contemporary mode of doing business, and the challenge of adaptation was made much easier by the flexibility of the authors.

Any errors, typos, conceptual gaffes, missed opportunities, or other glitches cannot be attributed to those who have just been acknowledged.

Paradigm Shift: The Past is Not the Future

Daniel J. Reschly
Vanderbilt University
James E. Ysseldyke
University of Minnesota

OVERVIEW

In this fourth edition of one of the most successful volumes in school psychology, the shifting paradigm toward services guided by problem solving and evaluated by the achievement of positive outcomes is increasingly apparent. In this chapter, we describe and contrast different paradigms for the design and delivery of school psychological services, analyze problems in the traditional delivery system, and review major policy and reform statements. The chapter concludes with a discussion of the knowledge base, underlying principles, and strategies that form the basis for psychological services that emphasize problem solving, functional assessment, and educational accountability.

The paradigm shift theme appeared in an earlier chapter we authored for *Best Practices in School Psychology* (3^{rd} ed.). Today, years later, we are even more certain of the paradigm shift than before based on (a) successful implementation of system reform in several states, (b) research results showing the irrelevance of IQ to the identification of students with high incidence disabilities, disabilities that account for 85–90% of all students with disabilities, (c) increasing knowledge of effective academic and social/behavioral interventions, (d) recommendations of authoritative reports such as the National Academy of Science's *Report on Minority Over Representation in Special Education*, and (e) increasing governmental support for systems that feature noncategorical eligibility and functional assessment.

SCHOOL PSYCHOLOGY AND CRONBACH'S TWO DISCIPLINES

Philosophical foundations for service delivery systems are important guides to how problems are conceptualized, assessed, and treated. Two contrasting philosophical foundations are the basis of the traditional delivery system and the alternative delivery systems emphasized in the school psychology literature since the mid-1980s (Reschly, 1988a, b). Correlational and experimental approaches to scientific psychology correspond closely to differences between current delivery system models (Cronbach, 1957). Cronbach described the two disciplines, correlational and experimental, as differing in (a) philosophical assumptions, (b) research methodology, (c) key variables and causal inferences, and (d) methods of promoting human welfare.

Correlational Discipline

The correlational discipline emphasizes assessment of the natural variations among people in cognitive, physical, and social-emotional domains. These variations are then related to actual performance in academic or employment settings. If there are significant relationships (correlations) between these natural variations and performance, then increased efficiency in the use of resources and enhanced overall performance can be produced by differential selection or placement. The correlational discipline attempts to advance human welfare by selecting the best-qualified persons for different careers, training programs, or instructional procedures. Cronbach suggested that the correlational tradition was more consistent with political conservatism in that the individual differences are typically seen as relatively immutable to change and the main outcome is to fit persons to existing programs.

Experimental Discipline

In contrast, the experimental discipline was seen as more liberal politically because the fundamental aim is to create higher levels of performance through, first, discovering the best interventions and then, second, disseminating and implementing the best interventions. Different treatments or interventions are contrasted carefully so that causal statements can be made about which had the highest average effects for groups of participants or, in single subject designs, for individuals. Careful control of experimental conditions was extremely important so that valid comparisons could be made between experimental conditions (i.e., treatments).

The fundamental differences between the two disciplines become more apparent in considering what each did with individual differences. The experimentalist attempted to create variations among persons who received different treatments and to minimize variations among persons who received the same treatments. The variation among persons receiving the same treatment was error, something that had to be controlled to the greatest extent possible. Experiments are rarely entirely successful. Some degree of variation among persons receiving the same treatment is virtually inevitable.

The fundamental phenomena studied in the correlation discipline are the more or less "natural" variations among persons, considered by the experimentalist as error variance. It is this natural variation that makes differential prediction possible. Non-significant or attenuated prediction accuracy results from the absence of variations among persons or artificially reduced variations. Interestingly, variations among persons or individual differences were fundamental to both disciplines; however, the predictor variables in the correlation tradition contributed to the error terms in the experimental discipline. One science attempted to produce differences while the other attempted to predict performance from existing individual differences and select more appropriate placements. In many ways the traditional and modern trends in school psychology parallel the approaches in the two disciplines.

Aptitude by Treatment Interactions

In the seminal 1957 article Cronbach suggested a merger of the two disciplines would produce maximum benefits. "For any potential problem, there is some best group of treatments to use and some best allocation of persons to treatments" (p. 680). The Aptitude by Treatment Interactions (ATI) approach involved the study of (a) differences among treatments, (b) aptitude differences among persons, *and* (c) the interaction of aptitudes and treatments. Based on the interactions, individuals would be assigned to the treatments that would produce the best results. The educational application suggested by Cronbach, greater emphasis on individual prescriptions, was the basis for much of school psychology over the past two decades, "... we should *design* treatments, not to fit the average person, but to fit groups of students with particular aptitude patterns.... We should seek out the aptitudes which correspond to (interact with) modifiable aspects of the treatment" (Cronbach, 1957, p. 681).

ATI is one of the most attractive ideas in all of basic and applied psychology (Arter & Jenkins, 1977, 1979; Ysseldyke, 1973). It is an idea that "should" work in the laboratory and in practice. The idea of matching treatment to naturally occurring characteristics of the person makes inherently good sense; clearly, it is consistent with our humanistic commitments of individualizing instruction and psychological treatments in order to maximize opportunities. ATI is especially attractive in school psychology where most of the work traditionally has been with individual children referred for learning and behavior problems. Unfortunately, what "should" work, what is inherently appealing, is not always a sound basis for practice. Such is the case with the efforts to use ATI as the foundation for applied psychology.

ATI Failure and Short-Run Empiricism

In less than two decades, Cronbach's frustration with ATI as a basis for applied psychology was palpable in another *American Psychologist* article, "Once we attend to interactions, we enter a hall of mirrors that extends to infinity" (Cronbach, 1975, p. 119). In the ensuing years between 1957 and 1975, Cronbach and colleagues conducted many studies in which attempts were made to identify interactions of aptitudes and treatments. Unfortunately, the hypothesized interactions often did not occur, were extremely weak when they did appear, and often were entangled in intractable and hopelessly complex higher order interactions that were virtually impossible to study in laboratory settings, let alone use in practical situations. Furthermore, potent interaction effects, when they did exist, were for prior achievement or skill levels within the domain(s) of behavior that was/were the dependent variable(s) in the ATI experiments. Indeed, level of prior knowledge or skills is an important variable in subsequent learning or performance; however, the effect of prior knowledge was not the kind of aptitude envisioned in Cronbach's grand design or in the school psychology applications of ATI.

In the 1975 article Cronbach abandoned ATI as the basis for applied psychology. The strategy he suggested to replace ATI was remarkably similar to the current emphases on accountability and problem solving strategies (see later discussion). In place of ATI, Cronbach suggested context specific evaluation and short-run empiricism, "One monitors responses to the treatment and adjusts it" (p. 126). Two realistic goals were proposed by Cronbach for applied psychology: "One reasonable aspiration is to assess local events accurately, to improve short-run control. The other reasonable aspiration is to develop explanatory concepts, concepts that will help people use their heads" (1975, p. 126). The use of short-run empiricism (problem solving), and the selection of behavior change or instructional design principles from the available literature (see later discussion of experimentally supported interventions), is the contemporary application of Cronbach's suggestions for moving beyond the rigidity and insufficiency of the two disciplines of scientific psychology.

School Psychology Applications

Parallels to Cronbach's two disciplines in traditional and modern school psychology are easily identified. Although experimental trends were apparent in the earliest roots of school psychology (Sandoval, 1993), most of school psychology's history has been devoted to practice that is consistent with the correlational and ATI bases for practice (Fagan & Wise, 2000; Reschly, 1988a, b, 2000; Christenson & Ysseldyke, 1989). The increasingly frequent use of single subject designs, Curriculum-Based Measurement with formative evaluation, and functional behavioral analysis represent the clearest applications of the experimental discipline in contemporary school psychology.

The correlational parallel occurs with traditional placement services in which referred children are assessed to determine if they meet the criteria for classification as disabled. Children with different score patterns on measures of current intellectual functioning and academic achievement, are often classified into different disability categories and placed in different educational programs for part or all of their school day. The differential placement is seen as necessary to allow children to benefit educationally because the general education program is inappropriate to their naturally occurring aptitudes (general intelligence and achievement), a classic application of the correlational discipline (Cronbach, 1957). The earliest roots of school psychology (Fagan, 1992; Fagan & Wise, 2000) and a substantial proportion of current practice involve assessment of children's aptitudes and achievement as the basis for placement decisions. This application of the correlational science is valid to the degree that the placements are different and beneficial for individuals, groups, or systems, an issue to which we will return in a subsequent section.

Change in special education and school psychology is needed. The old models based on the correlational science and identification of deficits has not produced sufficient results. Better results for all students are needed. We believe those better results can be achieved through adoption of an experimental science, dedicated to building competencies rather than focusing on deficits. First, we discuss the many reasons for changing the current system.

UNRESOLVED CHALLENGES IN CURRENT PRACTICE

A number of intractable problems exist in the current system that have not been resolved, and are not likely to be resolved with significant system changes. In this section we discuss those problems, followed by a section that discusses the outlines of a paradigm shift.

Nature of Current Practice

Survey studies of the practice of school psychology yield consistent results (Curtis, Hunley, Walker, & Baker, 1999; Hosp & Reschly, in press; Reschly, 2000; Reschly & Wilson, 1995; Smith, 1984). School psychologists devote about two thirds of their time to activities related to special education classification and placement, with slightly over half of the time devoted to individual assessment activities, usually with standardized measures of ability and achievement. These surveys also indicate that current practitioners prefer to spend more time in direct and indirect activities related to interventions such as individual counseling and problem-solving consultation. The value of the current roles and time allocations depends heavily on the benefits to students associated with classification as disabled and placement in special education programs. The key issue is, "Do special education categorical diagnoses such as emotional disturbance (ED), learning disability (LD), mild mental retardation (MMR) lead to category-specific treatments, and are those treatments differentially effective depending on the student's diagnosis?" The answer seems to be negative. Moreover, current practice is deficit-focused (i.e., dedicated to finding deficiencies in children's capabilities) rather than the enhancement of competencies. The current standards-based reform and accountability themes are highly influential in moving general education toward a competency enhancement focus, an influence that will be increasingly apparent in special education now and in the future.

Educational Accountability and Effectiveness of Special Education

The single greatest challenge in current practice is demonstration that students with disabilities and those who are at risk actually benefit from the educational programs, services, and interventions they receive. In the recent past, efforts to account for benefit usually involved attempts to demonstrate that *special education* was "effective." These efforts usually were combined with attempts to show that students benefited from being classified as mildly disabled and placed in special education. Multiple debates resulted from such effort because "effectiveness" was a function of the dual effectiveness of categorization practices and treatment practices. So, for example, researchers debated the effectiveness of classification and categorical practices (Ysseldyke & Marston, 1999), the cost/benefit of providing special education services (Chambers, Parrish, Lieberman, & Wolman, 1998), cost/benefit of prevention (Lee, Schnur, & Brooks-Gunn, 1988), and the effectiveness of instructional interventions based on aptitude-treatment interactions (Kavale & Forness, 1999), as well as in general (Ysseldyke & Marston, 1990). The reliability and validity of classification and categorical practices repeatedly has been challenged (Ysseldyke, Algozzine, & Thurlow, 2000; Ysseldyke & Marston, 1999). And, researchers indicate that assignment of differential treatment based on student ability, aptitude (ATI), or categorical condition has not produced especially promising outcomes.

More recently, researchers are examining the extent to which *education* works for students with disabilities. Investigations of treatment effects are considered independent of setting. While the shift from asking, "Does special education work for students with disabilities?" to asking "To what extent does education work for students with disabilities?" has been an important conceptual shift, and one that recognizes that students with disabilities are educated for the most part in general education settings, the treatment effects question still has not been answered.

So, what is the big deal. Why is this a problem? School psychologists spend most of their time classifying students, declaring them eligible for special education, and assigning treatments or interventions. In an era of accountability, school personnel and the general public want to know whether that practice is beneficial, and whether students are better off. Consider the following challenges we face:

1. Experimental studies of the effects of special education placements and settings cannot be conducted because students cannot be randomly assigned to different treatment conditions. Thus, researchers cannot conduct true experiments. They cannot examine the differential effect of general and special education for the same students, and they cannot examine the differential effect of special education for students who are and are not disabled. Efficacy studies must focus on individual treatment outcomes.

2. Chambers et al. (1998) report that "There are no comprehensive and accurate data sources that indicate what public schools in the U.S. are spending on special education services" (p. 2), and that "There are no current, uniform data sources that track expenditures for special education services at the federal and state level" (p.4). Current estimates suggest that, on average, the additional costs of special education are about 2.3 times the costs of regular education (Chambers, 1999). Special education is very expensive. Thus, it is important to ascertain the cost/benefit of special education services, and to make sure that the benefits are substantial.

3. Students with disabilities regularly and systematically have been excluded from large-scale state and district assessments. So, there are few data on their performance over time. For the most part we do not know, in the aggregate, how they are performing and the extent to which they are making progress. Such data are only available at the level of the individual student.

4. Very recently there have been significant increases in the participation of students with disabilities in assessment and accountability systems. When performance over time is tracked, the gap in performance of students in general and special education gets wider every year, with a continual decline in the performance of the group of students assigned to special education. Yet, as Bielinski and Ysseldyke (2001) showed, the gap in performance is confounded by annual reclassification of students from general to special education, reclassification from special to general education, and differential dropout.

5. Evidence for the effectiveness of treatments or interventions is best demonstrated at the level of the individual using a direct, frequent measurement approach (Reschly, Tilley & Grimes, 1999; Fuchs & Deno, 1991).

Given the failure of previous attempts to demonstrate the effectiveness of special education and of improved aggregate outcomes for students with disabilities, evidence of effectiveness is best demonstrated at the level of the individual, and through use of a problem-solving methodology with direct and frequent measurement.

Search for Pathology and Stigmatizing Labels

The search for pathology has dominated school psychology practice and special education eligibility and treatment to such an extent that few practitioners or researchers even consider alternatives (Ysseldyke, 2001). The search for pathology dominates eligibility evaluations and confers an overall, often implicit, obsession with deficits that deflects attention from effective treatment and the explicit pursuit of goals related to adult social roles. It is critical that assessment and treatment move away from the deficit orientation toward competence enhancement and capacity building at the individual and systems levels. Greater emphasis on enhancing competencies will be furthered by eliminating stigmatizing special education categorical labels, characterized accurately by Hobbs (1975) as:

> They are imprecise: They say too little, and they say too much. They suggest only vaguely the kind of help a child may need, and they tend to describe conditions in negative terms. Generally, negative labels affect the child's self-concept in a negative way, and probably do more harm than good (p. 102).

Alternatives to the current categorical special education eligibility system have been proposed and implemented (Reschly & Tilly, 1999; Tilly, Reschly, & Grimes, 1999). A non-categorical system works best with the traditional high incidence disabilities such as LD, MMR, and ED. Federal law now explicitly permits non-categorical approaches (see 34 C.F.R. 300.125). Non-categorical approaches facilitate placing more emphasis on gathering assessment information related to designing interventions that enhance competencies.

The Dilemma of Learning Disabilities

Nearly every system reform discussion focuses more attention on LD than any other category. There are many reasons for this emphasis; however, the primary reason is the dominance of LD in special education. Although there are 13 disability categories recognized in Individuals with Disabilities Education Act (IDEA, 1997, 1999), slightly over half of all students with disabilities are classified as LD.

LD is a dilemma for many reasons. First, the history of the LD field is replete with sharp disagreements over theory, research, and practice. The discussions of the essence of learning disabilities are reminiscent of the famous U.S. Supreme Court Justice's comment on pornography, "I know it when I see it." In fact, professionals have grave difficulty in identifying LD consistently across referred students, across different school districts, and across different states (Epps, Ysseldyke, & McGue, 1984; Gottlieb, Alter, & Gottlieb, 1999; Ysseldyke et al., 1983). Moreover, the prevalence of LD varies by a factor of three across the states (i.e., the highest prevalence state (Rhode Island) has three times as many students classified as LD as the lowest prevalence state (Georgia) (U.S. Department of Education (USDE), 1998).

Disagreements over intervention models also complicate the discussion of effective programs for students with LD. The process deficit model was dominant when LD was introduced in the 1960s as a comprehensive term referring to a variety of disorders previously called minimal brain dysfunction, dyslexia, perceptually impaired, and so on. The process deficit model was unsuccessful (Hammill & Larson, 1974; Kavale & Forness, 1999), although Naglieri and Das (1997a, b) are attempting to revive the notion that training cognitive processes such as planning can improve educational achievement. The rather bold claims made by these authors (Naglieri & Johnson, 2000) await independent replication.

The ATI model of LD intervention was conceptually similar to the process deficit model. Both emphasized deficit cognitive processes; however, the ATI model emphasized avoiding weak or deficit processes in the choice of teaching methodology, assuming that using intact processes would produce better results. The ATI model involving matching strengths and avoiding deficits is very popular as noted previously; however, there is no evidence that it works regardless of whether the processes are conceptualized as culturally specific learning styles (Frisby, 1993; Irvine & York, 1995), neurologically intact functions, cognitive styles such as simultaneous versus successive, modalities such as visual and auditory, and so on. Applied applications of ATI have the same outcomes as the laboratory work summarized by Cronbach (1975): ATI does not work as an LD intervention model (Kavale & Forness, 1999; Good, Vollmer, Creek, Katz, & Chowdhri, 1993).

Further, substantial attacks of current LD practices come from the Dyslexia Studies Centers funded by the National Institute of Child Health and Development (NICHD) (Lyon, 1996). The NICHD reading disability findings are increasingly influencing policy debates regarding LD intervention models and the usefulness of the widely adopted LD classification criterion of a severe discrepancy between ability and achievement. Diagnosis of LD through determination of the size of the ability-achievement discrepancy, involving administration of one or more IQ tests and one or more achievement tests, is *the* single most frequent activity of school psychologists. There are many problems with the use of the severe discrepancy criterion for LD eligibility.

First, the exact size of ability-achievement discrepancy is significantly less reliable than either of the tests used to determine the discrepancy. Nevertheless, significant decisions are often made about LD eligibility and allocation of thousands of dollars for special education services on the basis of a few points in the ability-achievement discrepancy. We have never met anyone who is certain that a 15- or 16-point ability-achievement discrepancy truly indicates greater need than a 13- or 14-point discrepancy. Moreover, nearly everyone acknowledges that repetition of the ability and achievement measurement a week later likely would change the size of the discrepancy. Although prominent in federal regulations (see 34 C.F.R. 300.541), the ability-achievement discrepancy is fraught with measurement error.

An even more fundamental issue about the use of a severe discrepancy to determine LD eligibility is the NICHD findings about separating poor readers into two groups: one with higher ability than reading achievement that is eligible for LD and a second group with relatively low reading achievement and ability that is not currently eligible for LD. According to the NICHD researchers this distinction on which nearly all of modern thought in LD rests is not valid!

> Results do not support the validity of discrepancy versus low achievement definitions. Although differences between children with impaired reading and children without

> impaired reading were large, differences between those children with impaired reading who met IQ-based discrepancy definitions and those who met low reading achievement definitions were small or not significant (Fletcher et al., 1994, p. 6).

The above criticisms of current LD classification practices are significant But there is more. The NICHD researchers have targeted the "wait to fail" phenomenon that is familiar to all school psychologists working in the early grade levels. It refers to a number of children who are referred for consideration of special education eligibility due to poor performance in reading. The initial referral often occurs at the end of first grade. The evaluation confirms poor reading achievement, but very frequently the ability-achievement discrepancy is not sufficient to classify the child as LD. The referral often is repeated in the second grade with the same result. The "wait to fail" children are often referred still again in third or fourth grade when, finally, the reading achievement is low enough in comparison to ability to meet eligibility standards. Unfortunately, the "wait to fail" phenomenon has harmful effects on children because, "For treatment, the use of the discrepancy models forces identification to an older age when interventions are demonstrably less effective" (Fletcher et al., 1998, p. 201; see also Fletcher, 1998).

Determination of ability-achievement discrepancies is a very substantial part of school psychologists' roles today in large part due to the federal regulation cited earlier (Reschly, 2000). It is highly likely that this practice will change in the near future. Currently, there is an Office of Special Education Task Force examining the LD issues and the implications of the NICHD studies. The NICHD studies severely undermine the rationale for the LD severe discrepancy criteria and the adoption by some states of alternative criteria that do not use ability-achievement discrepancies illustrate that other alternatives do work (Reschly et al., 1999). Moreover, states have enormous latitude in how disabilities are conceptualized and assessed including the option of not classifying students needing special education services by disability categories (see 34 C.F.R. 300.125; Tilly et al., 1999). The LD paradigm clearly is shifting with probable substantial influences on school psychology.

Intervention Integrity and Experimentally Validated Interventions

Further impetus for the school psychology paradigm shift comes from the late 1990s movement toward limiting interventions to those for which there is empirical support. This movement originated in the health professions where managed care companies increasingly restricted payments to health care providers such as physicians and psychologists for treatments that lacked data confirming effectiveness. The applications to school psychology sometimes appear under different terminology (e.g., evidence-based education, empirically supported interventions). The idea is the same as in the health care professions. Professional practices should focus on treatments or interventions for which there is data-based support. Moreover, stronger treatments are preferred to weaker treatments. Careful analyses of current roles find many poorly supported practices such as use of ability-achievement discrepancies to diagnose LD. Analyses of the effectiveness of various practices appear in the literature (e.g., Kavale & Forness, 1999) and problem-solving methodologies attempt to combine empirically validated treatments with continuous data collection and formative evaluation to ensure that these practices do in fact produce positive results for individuals (Fuchs & Fuchs, 1986; Tilly, this volume).

Related to the concerns about the empirical bases for many school psychology practices is the failure to implement many interventions as they were designed or intended. Basic intervention principles often are not implemented in IEPs, special education programs, and pre-referral interventions, and these interventions typically are not evaluated using individualized, treatment-sensitive measures. Intervention integrity or fidelity of treatment has a significant impact on outcomes (Flugum & Reschly, 1994; Telzrow, McNamara, & Hollinger, 2000) and systematic assessment of treatment integrity as well as outcomes will become increasingly prominent in school practice as the field responds to the demands for data-based practices.

Disproportionate Minority and Gender Representation

Disproportionate minority and gender representation in special education has come under increased scrutiny during the 1990s (MacMillan & Reschly, 1998; Reschly, 1997). Analyses of data from the U.S. Department of Education reveals a male to female ratio of approximately 2:1 in LD and 4:1 in ED. Moreover, representation patterns vary significantly by race/ethnicity with (a) Native Americans over represented in LD, (b) African-Americans in the MR and ED categories, (c) Hispanics slightly *under* represented in the several categories, and (d) Asian-Pacific Islanders markedly *under represented* in LD, ED, MR, and Speech/Language (USDE, 1998, 1999, 2000). Although many analyses of this issue have focused on testing and placement processes, the main issue is the effectiveness of special education programs for students with mild disabilities and the usefulness of school psychology services in overcoming patterns of low achievement. Major changes are needed in school psychology and special education in order to meet the concerns raised by disproportionate gender and racial/ethnic representation.

Paradigm Shift Policy Statements and Professional Association Policies

Attention to the most effective ways that school psychologists can promote the mental health and educational interests of children and youth has been prominent in the school psychology literature for at least five decades (e.g., Cutts, 1955; Gray, 1963). The current movement toward a paradigm shift and system reform has its roots in events that began about 20 years ago. The various events and statements are summarized briefly here with references provided for those interested in tracing the evolution of important themes. Two conferences on the future of school psychology set the tone for later developments (*School Psychology Review*, 1982; Ysseldyke & Weinberg, 1981). The futures conferences established strong assertions regarding the inadequacies of the traditional school psychology focus on determining eligibility for special education using standardized tests of ability and achievement, unreliable and invalid projective assessments of personality and psychopathology, and perceptual-motor measure of dubious merit. Alternative roles were explored in these conferences.

Themes in the futures conferences were further advanced by the products developed in the National School Psychology In-service Training Network (Ysseldyke, 1984) and by the first *Blueprint* that delineated the key competencies needed by school psychologists in order to assume new roles (Ysseldyke, Reynolds, & Weinberg, 1984). These themes were asserted even more strongly in two statements adopted as official policies by the National Association of School Psychologists (NASP) (1985, 1986). These statements emphasized the development of service delivery systems that were not driven by categorical labels. The debate over system reform was sharpened by an exchange of articles in a 1988 volume of *School Psychology Review* (Hynd, 1988; Kauffman, 1988; Reschly, 1988a, b). The foundations for system reform were vastly improved by two volumes published by NASP (Graden, Zins, & Curtis, 1988; Stoner, Shinn, & Walker, 1991; Shinn, Walker, & Stoner, 2002).

Improving assessment and linking assessment to intervention was the theme of a monograph commissioned by the federal government and developed by a team of NASP leaders (National Association of School Psychologists, National Association of State Directors of Special Education, Office of Special Education Programs, 1994). Attention to this basic theme and the development of effective interventions prompted the development of an updated revision of the *Blueprint* (Ysseldyke et al., 1997). Although 10 domains were specified regarding graduate education and practice, high levels of competence in four domains were expected of all school psychologists. These four domains might be seen as the core of school psychology training and practice:

1. Interpersonal communication, collaboration, and consultation

2. Student diversity in development and learning

3. Legal, ethical practice, and professional development

4. Data-based decision making and accountability

Perhaps most important to the paradigm shift is the crucial domain of data-based decision making and accountability. The *Blueprint* domains are consistent with contemporary trends regarding experimentally validated treatments (see prior discussion) and the movement toward comprehensive school mental health programs that stress prevention and early intervention (Adelman & Taylor, 2000; Nastasi, 2000). Finally, the publication of a volume in 1999 devoted to functional assessment and special education system reform provided further guidance to practitioners and policy makers regarding the school psychology paradigm shift (Reschly et al., 1999).

Summary

We are *compelled* by problems in the current system to consider alternatives to conventional referral, assessment, classification, and placement practices. These pushes provide the motivation to consider alternatives. Futures conferences, policy statements, blueprints for training and practice, and the professional literature over the past two decades have described the necessary changes in the delivery system that will permit the delivery of psychological services that are more closely related to the needs of children, youth, and families. In our discussion of these influences we know that we left out many important events and persons due to space limitations. We believe that the major themes especially in school psychology were addressed. Although the way to a reformed and more effective practice of school psychology has been charted in a general way, descriptions are needed of specific bodies of knowledge, assessment skills, and intervention competencies.

ADVANCES IN ASSESSMENT AND INTERVENTION

We are drawn to delivery system alternatives by advances in assessment and intervention techniques that have the promise to improve substantially the outcomes of educational services for children and youth with learning and behavior problems. Implementation of these alternatives has already produced a revolution in how school psychology is practiced and it is likely that further and more widespread changes in practice will occur as part of efforts to improve educational outcomes.

Accountability for All Through Outcomes Criteria

A major shift to a focus on outcomes rather than intervention inputs or processes is apparent in the reform literature. An outcomes orientation has been applied to analyses of over representation of minority students in special education and to a wide variety of other practice issues (Reschly, 1980; Reschly & Tilly, 1999). Greater attention to documentation of outcomes is pervasive in general and special education (Ysseldyke & Marston, 1999). The push to document the outcomes of education has its roots in concerns by business and community leaders about the relatively low level skills exhibited by the people they hire, and in concerns about the relatively low standing of American students in international comparisons.

For many years after enactment of the Education of All Handicapped Children Act of 1975 (now IDEA, 1997, 1999), accountability for special educators meant documenting the *processes* used to serve students with disabilities (e.g., due process compliance, multidisciplinary teams, parent involvement), *placements* following the least restrictive environment principle, and *services* that were based on comprehensive evaluations and written individual educational programs. Virtually no one asked whether these dramatic changes in how special education was delivered produced better results. Several federal laws changed the situation; the crucial question now is how effective are special education services in producing gains in *academic and social* domains for students with disabilities. A major feature of the new accountability is the mandatory inclusion of students with disabilities in district and state assessment programs (McDonnell, McLaughlin, & Morison, 1997; Ysseldyke & Thurlow, 1997).

Professional services by psychologists and educational programs change when an outcomes focus is established, particularly if accompanied by significant incentives and disincentives based on results. Practices and programs that cannot be linked to positive outcomes for students are diminished increasingly while those associated with good outcomes (i.e., are experimentally validated) increasingly expand.

Problem-Solving Orientation

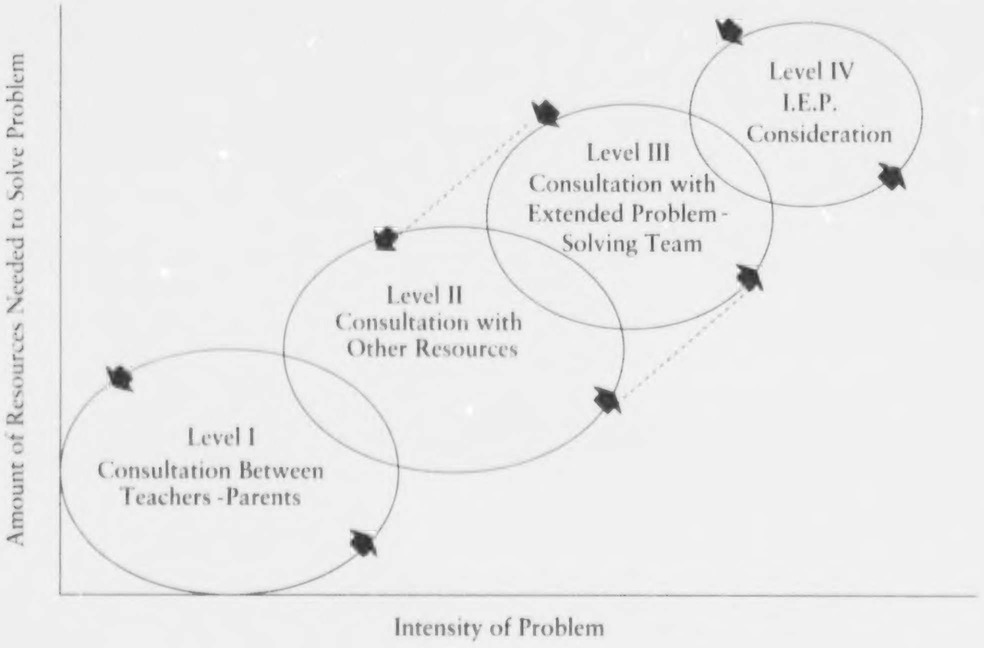
Rigorous, data-based problem solving is crucial to improving the student outcomes associated with school psychology services. Several problem-solving approaches have appeared in the literature, with slight variations related to intended population or type of problem (Bergan & Kratochwill, 1990;

Rosenfield, 2000; Rosenfield & Gravois, 1996; Tilly, this volume; Tilly et al., 1999). All have the common features of problem definition, direct measures of behaviors, design of interventions, monitoring progress with intervention revisions as necessary, and evaluating outcomes. All are more consistent with the experimental than the correlational tradition in psychology and the short-run empiricism described by Cronbach (1975) as a promising replacement for interventions guided by aptitude by treatment interactions.

Problem solving is an essential component of implementing advances in assessment and interventions. We caution against superficial versions of problem solving, particularly those that do not use precisely defined problems, direct measures of behavior, pre-intervention data collection, intentional application of instructional design and behavioral change principles, frequent progress monitoring with program changes as needed, and evaluation of outcomes through comparisons to initial levels of performance. As Fuchs and Fuchs (1992) noted, "feel good" consultation is likely to make the participants (e.g., psychologist and teacher) feel good, with little benefit to students.

Problem solving provides the overall structure for an alternative delivery system. Different levels of problem solving are illustrated in Figure 1, which represents the system developed by the Heartland Area Education Agency in Iowa (Ikeda, Tilly, Stumme, Volmer, & Allison, 1996). The four levels of problem solving involve different degrees of intensity and different levels of special education and support services involvement. The first two levels are conceived as occurring entirely within general education with occasional involvement of related services providers such as psychologists. Level III problem solving, involving related services personnel, is a rigorous, data-driven, intervention effort that must meet exacting standards for parental involvement, problem definition, systematic data collection, problem analysis, goal, intervention plan development, intervention plan implementation, progress monitoring, and decision making. Detailed standards have been developed for each of these problem-solving components (Tilly et al., 1999). Interventions meeting these quality indices must be implemented for a reasonable period of time and found to be insufficient according to progress monitoring data before Level IV problem solving (special education consideration) is initiated.

Figure 1. Heartland Area Education Agency problem-solving model



In Level IV problem solving classification of the student as needing special education may be considered based on documentation of (a) substantial discrepancies from average levels of classroom performance that (b) are not resolved to a sufficient degree by high quality interventions in general education, or behavioral discrepancies that (c) require programming elements or instructional intensity beyond the resources that reasonably can be provided in general education, and (d) there is a clear need for the kind of services provided in special education. Note that all four elements must be met. This system depends heavily on problem solving, curriculum-based and behavioral assessment, and high quality interventions. A critical eligibility criterion is resistance to intervention (Gresham, 1999), with rigorous standards established for quality of interventions. Further discussion of each of these areas appears in other chapters in this volume.

Although we strongly endorse the experimentally supported interventions movement, a problem-solving framework is essential even with the most effective interventions. Interventions are judged to be effective on the basis of group comparisons and the accumulation of single subject data. There are, however, *individuals* who are non-responders or whose responses to treatments are different than typical participants. A self-corrective problem solving methodology accounts for the individual responses to treatments, ensuring that what typically works does indeed work for an individual, or that interventions will be changed in the light of data indicating a weak or inadequate response.

Functional Behavioral Assessment

Functional behavioral assessment is emphasized in IDEA (1997, 1999) as an essential component of all special education eligibility and programming evaluations (see 34 C.F.R. 300.532). Significant advances in assessment technology permit greater emphasis on measures functionally related to interventions. Most of these advances can be classified as behavioral assessment procedures (Shapiro & Kratochwill, 2000). The knowledge base for practice has improved substantially with the development of curriculum-based assessment and Curriculum-Based Measurement (Howell & Nolet, 1999; Shapiro 1996; Shinn, 1998). Advances in the assessment of instructional environments provide further technological support to academic and behavioral interventions (Ysseldyke & Christenson, 2002). Parallel advances in behavioral assessment of social and emotional phenomena have led to equally substantial improvements in practice in these areas (Gresham & Noell, 1999).

We believe that assessment will continue to be a salient activity in the roles of school psychologists; however, vast changes will occur in assessment purposes, techniques, and outcomes. The focus will be increasingly on fostering behavioral competencies, rather than identifying deficits, through the implementation of direct measures of relevant behaviors in natural settings. The technology for that kind of practice has improved dramatically and continues to advance.

Instructional Design

Behavior assessment and instructional design are inextricably related in the functional assessment of academic behaviors. The marriage of instructional design principles (Becker & Carnine, 1980; Engelmann & Carnine, 1982; Howell & Nolet, 2000) with behavioral intervention technologies has produced impressive outcomes for students (Carnine, Silbert, & Kame'enui, 1997; Kame'enui & Carnine, 1998). Instructional interventions guided by experimentally validated methodologies, monitored with Curriculum-Based Measures, revised as necessary using formative evaluation rules, and supported by systematic reinforcement contingencies produces effect sizes of +1.0 standard deviation (SD; Fuchs & Fuchs, 1986; Kavale & Forness, 1999). The typical resource interventions or one-to-one tutoring interventions have smaller effect sizes in the range of 0.3 SD to 0.7 SD (Elbaum, Vaughn, Hughes, & Moody, 2000; Kavale & Forness, 1999; Swanson, 1999). Readers are urged to consult this literature in formulating approaches to academic skills teaching and remediation.

Behavior Change Principles

The continuing success associated with applications of behavioral psychology to a wide variety of learning and behavior problems is another crucial link from the scientific literature to current and future school psychology practice (Stoner, Shinn, & Walker, 1991; Shinn, Walker, & Stoner, 2002; Sulzer-Azaroff

& Mayer, 1991; Weisz, Weiss, Han, Granger, & Morton, 1995). The effect sizes of 1.0 SD or more for applied behavior analysis interventions regarding social, behavioral, and academic problems cannot be matched by any other intervention theory or approach (Kavale & Forness, 1999). Although other perspectives are sometimes incorporated into behavioral formulations (e.g., Dishion & Patterson, 1999), the fundamental basis of the vast majority of effective approaches continues to be an analysis of environmental influences and systematic changes in antecedent, situational, and consequent events. We believe that the increased effectiveness of school psychology and special education depends directly on better use of behavior change principles within a problem-solving framework.

Summary

The paradigm shift movement is based in advances in assessment and interventions that "pull" school psychology and special education toward system reform. One of the main themes in system reform is improved application of the available knowledge on assessment, instruction, learning, and behavior change. The movement toward non-categorical classification will place less emphasis on extensive psychometric testing to confirm eligibility and more emphasis on interventions guided by functional analyses of behavior, leading to implementation of effective interventions in academic and social-behavior domains. Paradigm shift will cause dislocations. New skills will have to be mastered and applied to resolve the contradictions between the new and old systems. Some of the key issues surrounding system reform are discussed in the next section.

Social and Political Validity of System Reform

We acknowledge the difficulty of change, but, at the same time, we observe that significant changes have occurred over the last 25 years. There has been a revolution in student rights and parental involvement in decision-making regarding the education of students with disabilities. For example, prior to about 1975 many school districts did not request parental consent for evaluations to determine eligibility for special education. These changes occurred very rapidly after federal court cases, state legislation, and then federal legislation mandated the implementation of the due process protections that are now taken for granted by most practitioners.

The example of the relatively rapid implementation of due process protections in special education is an illustration of another fact about system reform changes: they are driven more by political influences than data or science (Ysseldyke, 2001). The due process mandate was a political solution to a serious dilemma: How to ensure that special education decision making was fair and in the best interests of students. Similarly, we expect that system changes away from categorical designation of students with mild disabilities (e.g., LD, MMR) and the heavy reliance on standardized tests to determine eligibility will be political as well. We also note that science alone is unlikely to produce the changes that are needed; however, political shifts (e.g. accountability demands) combined with science (e.g., problem solving and experimentally supported interventions) are likely to produce the changes we have discussed.

Challenges and Consequences of Change

Change has obvious consequences and challenges for individual professionals. The major statements on system reform emphasize the importance of the *process* whereby reforms are designed and implemented. The system reform statement endorsed unanimously by the Delegate Assembly of the National Association of School Psychologists in March 1985 stressed, "the development and piloting of alternatives" as well as the "... need to assure that no child is put at risk for loss of services while the change process is occurring." (National Association of School Psychologists, 1985). Since 1985, NASP has devoted considerable resources to critical elements of system reform including policy advocacy and continuing education of school psychologists (Cobb & Dawson, 1989; Graden et al., 1988). Politically valid reforms have the critical elements of fair and equitable distribution of resources, involvement in decision making, protection of jobs, and continuing education opportunities (Jenkins, Pious, & Peterson, 1988).

Resource Allocation

System reform often involves development of different ways to fund programs. Two protections are critical. First, system reform cannot be allowed to become a way to reduce financial support of special and remedial programs for children and youth. The legitimacy of system reform requires at least stable resources. Second, alternative methods of funding programs and alternative resource allocation procedures should first be pilot tested in smaller units (e.g., a few districts, or regional units in a state) before applied to the entire system. This approach worked well in the Iowa system reform effort and is being implemented currently in other states such as South Carolina and Illinois.

Involvement in Decision Making

Constituents of the present system should be involved in decision-making regarding the des[illegible] of alternative delivery systems. Constituents should be viewed broadly, including related services professionals, special educators, general educators, parents, and children and youth. Leadership by psychologists is essential to successful system reform; indeed, the major advances in assessment and interventions on which reforms are based originated in basic and applied psychology! Ensuring that the available knowledge base is implemented is a crucial role for psychologists in system reform.

Protection of Jobs

Practitioners in the current system are asked in system reform to support significant changes that affect the kinds of professional roles that are valued and how they do their jobs. The roles of some practitioners may change dramatically. The legitimacy of system reform depends on guaranteeing the employment of these persons, at least in the short term, and providing for them ample continuing education opportunities to acquire skills that are needed in the new system. Each individual should get a fair shot at continuing their employment in a role that is valued if they are willing to acquire skills that are needed in the new system.

Continuing Professional Development

Continuing education opportunities are perhaps the single most important feature of system reform. Most of us have ample continuing education needs, expressed eloquently by one of our leading scholars, "I have saved my course notes from graduate school. With the exception of statistics, everything I was taught no longer is true" (Bardon, 1981, p. 202). The advances in assessment and intervention are not well represented in all graduate school psychology programs; indeed, it is our observation that many of us who are university faculty have continuing education needs that equal and, in most cases, exceed those of typical practitioners!

Traditional school psychology training provides an essential foundation for system reform that we can use as a base in meeting our continuing education needs. Our knowledge base in learning, normal and exceptional patterns of development, sensitivity to cultural differences, measurement, assessment, counseling methods, and relationship skills is unique among related services personnel and essential to successful performance of roles in new systems. To this traditional knowledge base we need to add systematic problem solving, consultation, principles of behavior change, principles of instructional design, and functional assessment.

The design of continuing education is crucial (Reschly & Grimes, 1991). Most current continuing education can be characterized as "train and hope" because actual supervised practice with feedback in implementation of new skills is not provided. Effective continuing education that leads to persistent changes in professional services requires a multi-step process; that is, (a) awareness and knowledge acquisition, (b) demonstration, (c) simulated try-out with feedback, (d) implementation in the work setting with feedback, (e) additional training opportunities to overcome problems that emerge in implementation, and (f) support and incentives for changing roles through performance evaluation and other mechanisms.

Paradigm Shifting and Leadership by Psychologists

The paradigm shift is occurring at different rates and in varying forms throughout the United States. There are, however, few states that have not been involved in special education reform, and the pace of change has quickened in the latter part of the 1990s. We acknowledge that paradigm shift does not occur quickly or easily; indeed, many unanticipated barriers have been encountered and will be encountered in the future. Despite the necessity to acknowledge significant impediments to reform, we remain optimistic about the delivery system and role changes described in this and other chapters in this volume. Our faith is based on a conviction that the delivery system and role changes are in the best interests of children, youth, and families, and that greater accountability and application of the outcomes criterion will increasingly invigorate and strengthen the support for a paradigm shift. Fundamentally, the paradigm shift involves a change from the correlational science of standardized testing, prediction, and placement to an experimental science of interventions designed to maximize learning guided by short-run empiricism-problem solving. Paradigm shift means making differences in, rather than predictions about, students' lives.

2 Best Practices in School Psychology as a Problem-Solving Enterprise

W. David Tilly III
Heartland Area Education Agency 11

OVERVIEW

Adoption of problem solving in schools is an explicit and systematic movement to import the scientific method into applied educational practice and eschew purely a "philosophical" basis for practice. All the sciences—astronomy, biology, chemistry, physics—had their roots in and eventually broke free from philosophy (Baum, 1994). Indeed all of the sciences reached a point in their development where philosophical reasoning, assumptions, and practice no longer sufficiently addressed problems at hand. In the very same way, traditional practice in school psychology and special education is no longer sufficient to address students with disabilities problems in our schools. A change is necessary in both (a) the way we think about special education and (b) the practices we use to accomplish service delivery. This chapter presents the conceptual and operational underpinnings of a problem-solving special education system designed to improve educational results for students with disabilities.

CHANGE IN THINKING

In philosophically based systems, a particular framework for reasoning is used. Philosophers reason from premise to conclusion: *If this is true, then that would be true* is the general logic form. The order of events is: *Premise leads to observation leads to conclusion.* In philosophy, truth is absolute: If the premises and the reasoning are sound, then the conclusions must follow. As an example of this logic, ancient chemists speculated that matter had certain properties such as wet, dry, cold, and hot. Given that these assumptions are correct, philosophers observed the world and concluded such things as fluid water has more of the "wet" quality and wood fires have quite a lot of the "hot" quality.

Much of our reasoning in current school psychology and special education practice follows this same logic set. The process of identifying students with learning disabilities is an example. The framers of the Education of the Handicapped Act (P.L. 94-142) wrote a series of assumptions into the law about the nature of learning disabilities (e.g., severe discrepancy, not based on presence of other disabilities, etc). Based on these assumptions, assessors spend much time observing the world in a very systematic way (i.e., testing), and then observing whether specific students have or do not have qualities reflective of learning disabilities. As before, if the premises and logic underlying the practice are sound, then so would be the conclusion.

When sciences emerge and break from their philosophical roots, a predictable process ensues. First, practitioners accumulate a growing number of anomalies that cannot be explained sufficiently using the accepted philosophical premises and reasoning. As a result, practitioners begin relying less on "accepted premises and conclusions" as the basis for study and begin observing natural phenomena as the basis for their analyses, which leads to a shift in the manner in which reasoning occurs. Scientists do not need apriori premises to form the basis for reasoning. Instead, scientists reason from observation to hypothesis to test to tentative conclusion. The general form is, "This is observed; what might be true that could explain this observation?" A test of the explanation then is devised. In science, truth is always relative, tentative, and able to be disconfirmed by further observation and investigation.

The break in special education and school psychology with the philosophical bases underlying much of our practice is beginning in many places. The predictable process depicted in the previous paragraph is underway. Educators and school psychologists have accumulated large numbers of "practice anomalies" that result from the failure of underlying assumptions and practices (Reschly & Tilly III, 1999; Ysseldyke & Marston, 1999). Examples include disability labels that typically do not provide sufficient information for effective treatment planning (Heller, Holtzman, & Messick, 1982), assessment processes that are often unreliable in differential diagnosis (Epps, Ysseldyke, & McGue, 1984), frequent use of assessment procedures without documented treatment validity (Howell, 1991; Salvia & Ysseldyke, 1998), and frequent implementation of poor quality educational interventions (Flugum & Reschly, 1993; Gresham, Gansle, Noell, Cohen, & Rosenblum, 1993). The logic sets that provide the foundation for much traditional practice have not, upon further investigation, resulted in the predicted positive outcomes for students with disabilities (Ysselkyke, Thurlow, & Bruininks, 1992). Thus, practitioners have begun looking elsewhere for solutions to intransigent educational problems.

Movement from philosophically rooted practice to scientifically based practice is a values-based set of actions driven by multiple factors. There are school psychologists who reject the idea that psychology or education should be addressed scientifically, and these positions are respected. However, in the current milieu, there are compelling rationales to move in this direction. These include:

1. Many of the assumptions underlying previous models of practice have been unsupportable in practice. For example, the idea that there are interventions that can be matched to student characteristics that predictably result in improved outcomes for students has not been borne out on a large scale (Arter & Jenkins, 1977; Kavale & Forness, 1987; Reschly & Ysseldyke, 1995). A problem-solving model does not rely on unproven assumptions of practice.

2. Legally driven, administrative practices are expensive and not predictably related to student improvement (Kavale, 1990). The current special education system invests much energy and resources into the administrative process of identifying individuals with disabilities. This focus siphons off resources that could be directed toward processes with documented relationships to student improvement. Problem-solving models require implementers to focus their attention primarily on educational rather than on administrative decisions. Thus, problem analysis, progress monitoring, and program evaluation decisions take on additional emphasis.

3. Improved technologies have become available in recent years that allow practitioners to become more effective in an intervention-based role (Gresham & Noell, 1999; Howell & Nolet, 1999). Most interventions in school psychology practice represent field-based implementations of research-based practice. All existing school-based practices must be evaluated in the context of other practices designed to accomplish the same purposes. With a burgeoning set of empirically demonstrated practices, ethical practice demands that we examine carefully current practices in light of emerging technologies for improving student performance.

4. The accountability movement is driving change in all of education (Marzano & Kendall, 1996; Thurlow, Elliott, & Ysseldyke, 1997). With the reauthorization of the Individuals with Disabilities Education Act in 1997 (IDEA 97), students with disabilities must now be included in state and district accountability systems and the results of their performance reported to the community. Increased scrutiny of educational programs for students who do not perform successfully in the general curriculum likely will be a byproduct of this movement. It is unclear at this point what effect this increased attention will have for students with disabilities. What is clear is that scrutiny has shifted in special education compliance at a federal level from examining primarily administrative practice (i.e., identification) to a more balanced approach

emphasizing results for students with disabilities (National Association of State Directors of Special Education, 1995).

5. Most importantly, despite our best efforts in educating students with educational problems, still many of them are not succeeding in school and after. Continuing with a model that is ineffective for large numbers of students without seeking more effective alternatives is ethically questionable and practically unwise. Thus, a move toward problem-solving structures is a data-based attempt to improve outcomes for students with disabilities.

Given these challenges, movement toward problem solving provides a major leadership opportunity for school psychologists to improve public education. Most of the skills necessary for effective implementation are those advocated by the National Association of School Psychologists (NASP) (Yesseldyke et al., 1997) *School Psychology: A Blueprint for Training and Practice II*. As a result, school psychologists are positioned well to lead problem-solving efforts and to assist educators in improving educational practice.

PROBLEM SOLVING AS A SYSTEM STRUCTURE

Moving special education toward a problem-solving proposition requires changing both system structures and practices within the system. The historical system grew out of legal mandates (EHA, IDEA) that dictate many structures and practices in special education. From Individual Education Plans (IEP) development through procedural safeguards and due process provisions, special education structures have remained fixed for more than 25 years. How might a shift to a problem-solving structure occur if so many things are dictated? The answer is that the "whats" of special education are fixed. For example, no matter where one lives in America, students with disabilities are guaranteed heightened due process, procedural safeguards, quality assessments, and IEPs. Considerable variability in "how" these "whats" are carried out is allowed to states by the Federal Office of Special Education Programs (Hehir, 1996; Tilly, Reschly, & Grimes, 1999). For example, states have wide latitude in how special education identification, assessment, and programming is carried out. One state may use a simple discrepancy process for identifying students with learning disabilities, another might use regression-based formulae to identify similar students, while a third state may use functional assessment procedures and non-categorical identification procedures. All can be legal. What is critical is that districts and states ensure that they meet the basic requirements of law.

Shifting structures in special education requires rethinking some of the assumptions underlying how our system was structured originally. Most important is rethinking how services can be delivered in direct relation to need. States and districts in most cases have organized their services typologically. That is, students with different types of needs are grouped together to make service delivery to these students efficient (consider Talented and Gifted Education, Title 1, and Special Education as examples in our schools). Underlying this practice is the assumption that students' needs exist in discrete groupings (Ysseldyke & Marston, 1999) and that discrete groupings for service delivery will thus meet students' needs optimally. In reality, student needs exist more on a continuum. Some students need more or less services than others both within and across different "typologically labeled" groups.

The solution to this situation is to create ways that service intensity can be varied in direct proportion to individual student needs both within and outside special education boundaries. This situation is desirable from a student learning standpoint and cost efficient from a resource allocation standpoint. Instead of waiting for students to fall so far behind that their performance qualifies them for special education, resources can be expended within a problem-solving system early, when problems are less intense, in the hope of remediating them prior to their escalation.

One problem-solving model that accomplishes the goal of matching resources with problem intensity is the Heartland Problem-Solving Approach (Heartland Area Education Agency, 2001a). This model will be described because it is a general-case model that includes desirable characteristics from a number of different problem-solving models. Moreover, it has been implemented successfully in practice for more than 10 years, so its viability has been tested empirically.

In the Heartland Problem-Solving Approach (Figure 1), the abscissa represents the intensity of the edu-

cational problem experienced by the student. The scale ranges from low intensity problems to high intensity problems. The ordinate represents the amount of resources necessary to resolve educational problems. The circles in the center represent the ideal match between the intensity of any given problem and the amount of resources that may be warranted to address the problem.

Parents, teachers, counselors, school nurses, principals, building assistance teams, community providers, or others having direct contact with students may express concerns and initiate problem solving. In the Heartland model, assistance can be provided to students at any of four levels. These levels vary in terms of precision of problem identification, depth of problem analysis, as well as in systematicity and amount of resources brought to bear on the problem. Level I problem solving involves parent-teacher collaboration for addressing problems. At Level II, other teachers contribute expertise along with the primary teacher and parents to solve the problem. At Level III, related service persons such as school psychologists guide the problem-solving process with the other participants. Level IV continues problem solving at even a more intense level, and one of the questions addressed at this level is entitlement for special education (note that Level IV represents the smallest circle in the diagram, depicting that relatively few educational problems get to this level). At Level IV, problem solving continues. The only administrative difference is that in some cases, special education resources may be used to address students' educational needs as part of the problem-solving process. The next section describes briefly problem-solving practices at each of the four problem-solving levels.

LEVEL I: CONSULTATION BETWEEN TEACHER-PARENT

Level I problem solving typically begins when a parent or teacher has concerns about an individual child's performance. Problems can arise in any educational performance domain and there is no limit to the types of problems that might be addressed at this level. Typically a conference will be held between the teacher and parent(s) where a plan of action will be crafted.

At Level I, teachers and parents focus their attention on specific behavior(s) of concern. Typically they discuss the nature of a problem and consider strategies that may be effective. They then determine a course of action to follow and informally monitor whether the intervention works. At Level I, related services persons are not involved with defining the problem or implementing general education interventions. Indeed, Level I simply acknowledges the informal problem-solving system that has been used for decades within our schools. Level I practices are described in greater detail in Ikeda, Tilly, Stumme, Volmer, and Allison (1996). Level II problem solving begins when Level I has not been successful, or when either the parents or teacher determines there is a need for additional resources.

LEVEL II: CONSULTATION WITH OTHER RESOURCES

The purpose of Level II problem solving continues to be resolving the presenting problem. At Level II, additional resources are brought to bear on the problem, the processes are a bit more structured, and information from Level I problem solving provides the initial input into Level II problem solving. Components of the Level II process include (a) to more systematically gather information about the severity of the problem, (b) to re-define the problem if necessary, and (c) to develop and monitor new plans to address the problem. At Level II, most schools use assistance teams to address problems. These assistance teams consist of the child's parents and teacher, other teachers in the school, and local support staff (such as the guidance counselor) to the extent appropriate. Additional staff from outside of the school or the student also may participate on the team if deemed desirable and appropriate by the team.

During the initial Level II meeting, the assistance team discusses the concerns surrounding the performance of the child. Through this discussion, the assistance team serves as a resource to the teacher and the parent. The team helps clarify the nature of the problem further and offers strategies that the classroom teacher can use to address the problem. Parents and the teacher agree upon one reasonable intervention for addressing the problem. The team then decides each member's role for assisting with the intervention and develops ideas for evaluating the intervention. The intervention is implemented, and if performance does not improve, then the general education intervention is refined. This process recycles as often as needed.

Evaluations at Level II also help the school determine if accommodations under Section 504 of the Rehabilitation Act of 1973 are required. In this way, one problem-solving process can meet the requirements of multiple programmatic requirements. If a 504 plan is deemed appropriate, accommodations are implemented to support the child in the particular problem area. Ongoing monitoring of interventions helps gauge the effectiveness of accommodations. This frequent review allows only those accommodations that are helpful to be continued. If interventions and accommodations at Level II do not change the behavior at desired rates or to desired levels of performance, then the child is referred to the Extended Problem-Solving Team for further consideration.

LEVEL III: CONSULTATION WITH EXTENDED PROBLEM-SOLVING TEAM

As illustrated in Figure 1, Levels II and III of the problem-solving overlap and are connected. These connections illustrate that in some cases the processes and procedures used at these levels overlap. The primary distinction between Level II and Level III is that related service personnel with specialized expertise and techniques are significant members of the Level III extended problem-solving team. School psychologists, instructional consultants, school social workers, speech and language pathologists, occupational therapists, and physical therapists among others all can participate in problem-solving activities at Level III. At this point in the process, the purpose of their involvement is neither special education assessment nor programming, but instead the purpose is to help resolve the presenting problems in general education. To this end, a systematic and structured deployment of general education resources will be undertaken by the Extended Problem-Solving Team at Level III.

At Level III, the Extended Problem-Solving Team reviews all information collected at Level I and Level II to begin their analysis. They examine whether the problem was identified accurately at Level I and Level

II and the effectiveness of interventions to date is reviewed. The team also ensures that all appropriate screenings (e.g., hearing, vision, health) have been conducted to rule in or out other plausible contributors to the problem. Based on these data, the team uses a standardized thought process to guide their next steps (Heartland Area Education Agency, 2001b). The team specifies an assessment plan to guide collection of additional problem-related information. Data then are collected to determine the nature and severity of the problem (problem identification) as well as to analyze problem etiology (problem analysis). At Level III, the problem analysis will be systematic and more in depth than at Level I or Level II. That is, an explicitly articulated thinking process will be used in problem analysis. This thinking process involves the integration of information from multiple sources with research-derived knowledge and experience in the problem area to specify and test hypotheses regarding specific etiology of the observed problems. Based on the problem analysis, an intervention plan with a high likelihood of success can be written. As a part of this plan, specific goals are written, and a progress monitoring plan—including a decision-making plan—are put in place. The intervention then is implemented and its effectiveness evaluated. The most critical distinction between Level III and previous levels is that Level III requires practitioners to use a structured thinking process and specialized tools to assist in the problem-solving process. It is at this level where specific professional standards of quality problem solving have been defined (Iowa AEA Directors of Special Education, 1994) that serve as expectations for practitioner performance.

Implementing general education interventions through problem solving at Level I through III has not delayed special education service to students. Indeed, services have been brought to bear earlier on educational problems than would have been the case in previous systems. What has not happened is a simple movement of an educational problem from general education to special education without a systematic and thorough examination of potentially effective uses of general education resources. One key to understanding this perspective is to examine how the word "help" is used in our educational vernacular. If "getting a child help in school" means referral for a special education entitlement evaluation, then the problem-solving system certainly may use more time. If, however, "help" means providing the least intrusive services that remedy the problem, in the most enabling environment, then problem solving in general education is a preferable initial response to educational problems.

One question often asked about a problem-solving system is, *But doesn't the law require entitlement evaluation for all students who are suspected of having educational disabilities?* The short answer to this question is yes. However, for students to be entitled to special education services, they must both have an educational disability and need special education in order to receive a Free Appropriate Public Education (FAPE; IDEA 97). To provide needs-based, problem-solving services, this is one place where it is critical to think differently about historical special education practice. While IDEA 97 continues to require determination of both disability status and need for special education prior to conferring entitlement on any individual, the law does not prescribe an *order* in which these two tests must be attended to. Hence, for a child experiencing problems in a general education setting, if a direct assessment is conducted for the purpose of general education intervention, and the resulting general education intervention is successful in remediating the student's skill or performance problem, then the question of special education entitlement is moot. An individual may in fact have an IDEA-eligible disability. However, if they do not need special education in order to receive a FAPE, they are not entitled to special education services, and therefore no delay has occurred.

LEVEL IV: PROBLEM-SOLVING INTERVENTION AND ENTITLEMENT CONSIDERATION

In moving to Level IV, the extended problem-solving team acknowledges that special education resources may be warranted to address a student's educational problems. When taking a case to Level IV, all the due process and procedural protections available under IDEA are provided. One of these protections is asking parents for written permission to have their child evaluated with the intent of determining special education entitlement. It is at this point where special education entitlement becomes a consideration and thus parental notice and permission is sought.

Entitlement for special education is only *one* of the questions addressed at Level IV. The purpose of Level

IV problem solving continues to be determining interventions necessary to address student needs, including whether required interventions include special education services. As a result, the focus of assessment is on direct student performance and environmental variables that are modifiable and directly related to student learning (e.g., curriculum, instruction, the learning environment). During Level IV assessment, extensive record review is conducted since a large portion of the information necessary for the special education entitlement decision has been gathered throughout problem solving Level I through III. Additional problem-solving assessments are then conducted to address additional factors related to improving the student's learning. Specific procedures and criteria for identifying educational disability in a problem-solving system are beyond the scope of the current chapter. A detailed description of these procedures and a rationale for their use can be found in Tilly, Reschly, and Grimes (1999).

The important point to glean from the foregoing discussion of Level I through IV is that the problem-solving structure allows resources to flow to problems in direct proportion to problem need. It is a rational alternative to past typological resource deployment systems and is synchronous with emerging accountability needs in education.

In addition to the use of a problem-solving *approach* as a resource-deployment structure in schools, problem solving is also a structured thinking process that is used to attack problems directly. In Heartland, this thinking structure is referred to as the problem-solving process. Each of the circles in Figure 1 represent one application of the problem-solving thought process in practice. The problem-solving process is the same at every level of the process and recycles multiple times as interventions are carried out for an educational problem. Attention is now turned to describing the problem-solving process.

PROBLEM SOLVING AS A SET OF PRACTICES WITH A CONSISTENT LOGIC SET

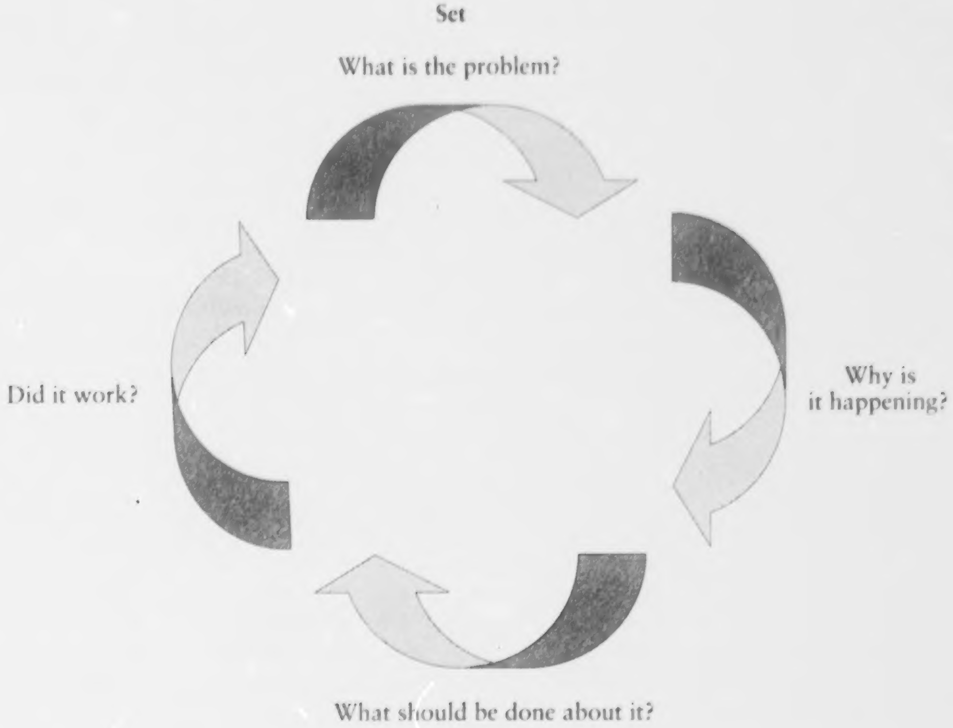
Many models of school psychological and educational problem solving exist, whether explicitly or implicitly referenced as such. These include Behavioral Consultation (Bergan & Kratochwill, 1990; Kratochwill & Bergan, 1990; Sheridan, Kratochwill, & Bergan, 1996); the IDEAL problem-solving model (Bransford & Stein, 1984); Functional Analysis of Behavior/Functional Behavioral Assessment (Repp & Horner, 1999; Tilly et al., 1998); the Scientist Practitioner Model (Barlow, Hayes, & Nelson, 1984); Curriculum-Based Measurement (Deno, 1995; Shinn, 1989); Applied Behavior Analysis (Baer, Wolf, & Risley, 1968); Action Research (Calhoun, 1994); and Heartland AEA's Problem-Solving Model (Reschly & Ysseldyke, 1995). Each model contains unique features, protocols, and language. In some cases, specific philosophies of science or theoretical orientations predominate, and differential emphasis is placed on alternate parts of the process.

No matter which specific approach or model of problem solving is considered, four thematic questions guide practitioner thinking: What is the problem? Why is it happening? What should be done about it? Did it work? A graphic depiction of this problem-solving logic set is contained in Figure 2. Clearly, problem solving is a logical process that most people do every day, which adds to its practical appeal. Problem-solving practices are intuitive, easy to understand, and easy to explain to parents and teachers alike.

The problem-solving thinking process applies equally to problems at every level of intensity, severity, and durability. What changes at different levels is the systematicity, rigor, precision, resource intensiveness, and possibly the intrusiveness of the tools and procedures that are used to accomplish the thought process in practice. For example, a small problem that may warrant a parent-teacher conference will not necessitate the same precision in problem identification, analysis, intervention, and evaluation as would a long-standing problem that deeply affects a student's quality of life. However, the same thinking logic could be applied to both circumstances. This consistency of thinking is an important component of the problem-solving process. Indeed, learning to apply and internalizing the thinking structures in the problem-solving process is perhaps the most critical variable in being able to implement it in practice.

The next section illustrates the reasoning that occurs when addressing each of the four problem-solving process questions. The synthesis is experience-based, success driven, and for continuity will be based on practice within the Heartland Problem-Solving Model presented earlier. This analysis will

Figure 2. Problem-solving logic



address only the *thinking processes* attendant to the questions as opposed to procedural steps. Critical problem-solving assessment and intervention tools are beyond the scope of this chapter and have been detailed elsewhere (Flugum & Reschly, 1993; Tilly & Flugum, 1995; Upah & Tilly, this volume).

What is the Problem or Issue?

In educational problem solving, it often makes sense to define problems as the difference between environmental expectations and what an individual does. Problems defined this way reflect naturalistically and accurately situations in educational settings. Indeed, most educational problems are brought to light when student performance deviates significantly from teacher expectations in classrooms. No matter where a problem falls on the severity scale, from mild through severe, the same thinking predominates in problem definition. Two things must be operationalized: What is the individual expected to do? What are they actually doing? The *difference between these two measurements represents the problem*, not the behavior that is the subject of the problem solving. This distinction may appear trivial. It is not. For example, physical aggression is not a problem if it occurs at the expected zero rate. The discrepancy between expectancy and performance in this case is zero—no problem. If, however, a student is expected to turn in 70% of her homework in order to pass her American Government class and she is turning in less than 20%, then there is a 50 percentage-point discrepancy between expectations and her actual performance—a substantial problem in most high schools. That the problem resides in the discrepancy is a key problem-solving concept that typically is easy to grasp.

In practice, substantial professional judgment must be exercised when defining problems. Judgment is required, for example, in selecting a standard against which to judge a student's performance. Clearly, the selected standard of comparison exerts great influence on the size of discrepancy observed, and thus care must be used when selecting an appropriate criterion. There are many appropriate standards to which a student's behavior might be compared. Professional experience, teacher preference, parental expectations, medical standards, needed skills in a future environment, curriculum standards, national norms, and local peer performance are all examples that could provide information on "expected" levels of student performance.

Selecting a performance standard representing acceptable performance can sometimes be tricky. Assessors must consider fairness and ethical and measurement issues in their selection, lest unfair or inappropriate problem identifications occur. Most often peer performance in the setting of interest can be used as an accurate indicator of acceptable levels of functioning. Peer performance has the advantage of representing typical performance locally, taking into account many variables (e.g., acculturation, regional differences, learning history differences, individual teacher biases) that may render other performance standards inappropriate. Once the comparison standard is selected, it is typically a straightforward process to create a measurement system that will allow direct measurement for both the standard and student performance. Once performance has been measured, simple arithmetic can be used to objectively scale the discrepancy.

There are important implications of defining problems as discrepancies. First, a discrepancy or difference score causes problem solvers to become objective about the nature of a problem. Important problem-related variables are defined in a way that promotes agreement about "what the problem is" by all involved parties. When there is objective agreement regarding a problem, there also can be objective agreement "that the problem is improving" as interventions are effective. Second, discrepancy-based problem definitions allow direct scaling of problem magnitude. The larger the discrepancy between observed performance and the standard, the larger the problem. Third, discrepancy-based problem definitions most often are created based on naturally occurring units of behavior, which usually lend themselves directly to analysis and intervention. For example, if a behavior of concern (response class) is aggression, direct measurement of the problem may include counting all incidents of kicking, hitting, or throwing of projectiles within a time span. The number of acts could then be compared to a peer standard collected during the same observation periods. The same problem could be quantified less directly through rating scales or personality tests that yield a standard score, a diagnosis, or description of personality variables. The former problem definition in this case lends itself directly to clear analysis and intervention using clearly articulated procedures with a high likelihood of successful resolution of the problem (O'Neill et al., 1997). The latter process may not.

The scientific method requires observation to drive hypothesis. When problems are defined in naturalistic behavioral units as discrepancies between what is expected and what occurs, direct observation drives problem analysis (i.e., hypothesis generation). The problem identification phase of problem solving tracks directly to the first state of scientific investigation; that is, observation of the environment as the basis for further analysis. Precise tools that yield consistent, objective measurement are used to provide a clear, unambiguous index of the situation. Problem definition then sets the stage for the second problem-solving phase: problem analysis.

Why is the Problem Occurring?

After operationalizing the problem, an analysis of problem etiology ensues. The purpose of problem analysis is to identify interventions for student problems that are (a) directly and empirically linked to problem occurrence and (b) have a high likelihood of successful outcome. Low level inferences predominate. That is, inferences are typically made about student skills rather than abilities, inferences are made about student behaviors rather than the traits the behaviors may represent, and most importantly inferences are made about the relationships between observed student performance and the highest likelihood variables related to observed performance. The necessity of low-level inferences in turn drives the types of assessments that are completed to assist in problem analysis. In most cases, problem-solving assessors move away from assessments of student disability to measures of student ability. Indeed, one school psychologist has captured the concept underlying problem analysis when describing its purpose as "Diagnosing the Learning Enabled" (Jeff Grimes, personal communication, 1998). Instead of measuring student performance to find disabilities, our purpose is to diagnose the conditions under which students' learning is enabled. Assessment for problem analysis requires quite different skills and procedures from those traditionally used in special education entitlement assessments.

The key to effective problem analyses is crafting clear summary statements or hypotheses that plausibly link (a) observed performance to (b) presumed causes (i.e., deduced from direct observation) of the performance problems which in turn lead to (c) treatment recommendations with a high probability of success. The general form of the logic is:

1. *For skill problems (can't do issues):* X problem is occurring because of Y. Therefore, if we do Z, the problem will be reduced (recall here that the problem is represented by a discrepancy).

2. *For performance problems (won't do issues):* When X antecedents occur, student name does Y in order to description of contingency. Therefore, if we do Z, the problem will be reduced.

The interventions represented by Z are thus logically linked to the analysis of the problems. Variables that served as targets for the problem analysis often in this case translate directly into actions that can be taken to enable learning.

As with problem identification, the critical shift in assessment for problem analysis is in thinking. The thinking shift in turn drives practice shifts. Rather than selecting tests for their technical characteristics and marketing, most competent problem-analysis assessments do not rely on published tests at all. In most cases, materials used for these assessments are selected directly from the materials and situations the student is working with in school. While these materials may not have been validated empirically for the purpose of disability identification, they operationalize the performance demands of the present environment and consequently are the most performance-valid assessment materials available.

Operationally, problem-solving assessors need to be able to tease out variables related to observed levels of performance in relation to direct environmental demands. The difference between problem-solving practice and historical practice is illustrated in the following example where two different approaches to analyzing the same student's reading problems are presented. One assessor may describe a student's reading performance as two standard deviations discrepant from their verbal ability with possible emotional overlays. These factors may indicate the presence of dysphonemic dyslexia, which may lead to prescribing a multi-sensory approach to reading instruction. Impressive sounding words, but not particularly helpful from an instructional perspective. What exactly is dysphonemic dyslexia? What specifically does it mean for this particular student? What skills does the student have and not have? What is the probability that a multisensory approach to instruction will work with this student and not with other students? What functional increment of information does the assessment process add?

A problem-solving assessor would likely assess the same student's reading skills directly. A sample of the student's oral reading would be collected. Specific-level tests (specific tests of component reading skills) would be given in priority order (skills with the highest probability of contributing to the reading problem are assessed first) and yielding a general picture of the student's component reading skills. Resulting analyses might hypothesize that the student's reading comprehension deficits result from (a) a lack of direct phonics instruction which has caused the student to read disfluently, (b) the student does not link new information to prior knowledge, (c) the student does not understand critical vocabulary words in the passages read, and (d) the student does not monitor meaning while reading. These data-based observations then would be used to develop a need specific intervention program tailored to the individual student. The difference between the former and latter reading assessments is their ability to directly pinpoint the specific skills that a student does or does not have and the level of inference needed to program instruction. As a general rule, the higher level the inference used to prescribe instruction, the less certain we can be in the effectiveness of the intervention prescribed.

Professional judgment and experience play a significant part in the analysis of problems as they did in problem identification. Indeed, it is not possible in problem-solving systems for assessors to competently analyze student performance in any performance domain if the assessor does not have significant knowledge in that domain. More than any other component of problem solving, problem analysis requires assessors to have broad and deep knowledge about the subject matter they are assessing. It is not possible to competently analyze the etiology of developmental reading problems if the assessor does not understand the process of learning to read. In the same way, it is not possible to discuss the etiology of behavior problems without reference to an accepted professional framework for understanding behavior. The content knowledge and experience requirements placed on assessors are perhaps the greatest professional development challenge associated with implementation of a problem-solving system.

The problem analysis phase of problem solving corresponds directly to the second stage of scientific investigation, that of creating hypotheses regarding variables that could plausibly explain the occurrence and nonoccurrence of the problem. To assist in hypothesis development, assessors can use whatever diagnostic measurements they choose, but those with most utility are those that measure student behaviors most closely resembling the behaviors that are considered problematic in the natural environment.

What Should be Done About It?

Once problems are defined and analyzed, the most complex part, if not the most challenging part, of problem solving is completed. When problem analysis is completed with integrity, reasonable environmental modifications with plausible connections to problem remediation usually become apparent. At this point, based on data collected from problem identification and problem analysis, educational interventions can be put in place.

There are a series of components that need to be thought through in setting up interventions. An intervention is defined in this context as a planned modification of the environment made for the purpose of changing behavior in a pre-specified way. Specifically, who will do what, when, and in what manner needs to be determined. A specific goal for the intervention may be set in measurable terms and procedures for monitoring the effectiveness of the intervention must be put in place. Any supports or materials that will be needed to carry out the intervention need to be created, and any training for implementers needs to be completed if necessary. An expanded discussion of educational interventions can be found in Upah and Tilly (this volume).

It is important that multicomponent interventions are considered for significant problems to ensure the highest likelihood of success. Not all components will be necessary for every intervention. However all of the components should be considered thoughtfully in all cases. Intervention components that should be considered when building educational interventions are presented in Table 1.

The intervention process in education is analogous to the component in the scientific investigation process that tests hypotheses. In this instance, educational programs are put in place, based on reasoned hypotheses (derived from problem analysis) in an attempt to confirm the accuracy of the problem analysis (hypothesis). Just as experiments in science are conducted to allow inferences to be made about hypotheses, so interventions in education allow us to draw inferences regarding the accuracy of our hypotheses—and to improve student performance in the deal.

Did It Work?

The final question addressed by the problem-solving process regards evaluation of interventions, both for-

Table 1. Intervention components

- *Antecedent interventions*: What changes can be made to the environment to prevent the problem from occurring?
- *Alternative skills instruction*: What skills can be taught to the individual that will reduce the occurrence of the problem?
- *Instructional consequent strategies*: What changes can be made to the instructional process to reinforce new skill acquisition and diminish problem occurrence?
- *Reduction-oriented consequent strategies*: What consequences, if any, need to be put in place to reduce the occurrence of the problem behavior?
- *Long-term prevention strategies*: What other individual or situational factors can we support to improve the individual's functioning?
- *Support for team members*: What support needs to be provided to team members to enable them to contribute to the intervention in an optimal way?

Adapted from Tilly, Knoster, Kovaleski, Bambera, Dunlap, and Kincaid (1998).

matively and summatively. Since it is not possible to predict with certainty the effectiveness of any educational intervention prior to its implementation, a progress monitoring process must be put in place to evaluate intervention effectiveness. As with other components of the problem-solving process, procedures used to monitor progress vary in their rigor, precision, and comprehensiveness. The important feature of progress monitoring systems is the ability to accurately illustrate progress over time. Typically, the behavior that was used to operationalize the existence and magnitude of the educational problem is used as the indicator of progress in progress monitoring systems. Data are collected multiple times per week, and a pattern of behavior emerges over time, which is often depicted graphically. By using systematic procedures and decision rules (Kazdin, 1982) to examine the pattern of performance the effectiveness of an intervention can be determined. Extensive resources are available on monitoring student performance (Alessi & Kaye, 1983; Kazdin, 1982; Parsonson & Baer, 1978; Shinn, 1989; Sulzer-Azaroff & Mayer, 1991).

At some point during intervention, the magnitude of the problem is revisited. A process very similar to procedures used to identify the initial problem ensues. Student performance is measured and compared to a standard of acceptable performance and a performance discrepancy identified. Two standards of comparison now are available to assist in evaluating the magnitude of the discrepancy. As before, current performance can be evaluated against the criterion of acceptable performance, and the size of the problem can be gauged in an absolute sense. Also, the size of the discrepancy can be evaluated in light of the size of the discrepancy at the time of problem identification.

The program evaluation component of problem solving is analogous to evaluation of hypotheses in scientific inquiry. The intervention provides the basis, and the monitoring and measurement provide the evaluation. Generally, if interventions work in improving performance, an inference can be drawn that the analysis of the problem was accurate (our hypotheses are supported). More precisely, the analysis was sufficient to result in significantly improved performance. In applied practice, this level of support for the analysis is sufficient. For problem solvers, the purpose of their efforts is socially meaningful behavior change. When intervention efforts result in this outcome for clients, universality of hypothesis application is secondary.

IDEA'S PROBLEM-SOLVING EMBRACE

There is a subtle, though important shift in thinking about assessment contained throughout IDEA 97. This shift has yet to receive much attention nationally. Instead it is the "new, high profile" assessment issues that have garnered most of the air time to date. These include the Functional Behavioral Assessment requirements attendant to the discipline provisions and the requirement to include students with disabilities in large-scale state and district assessments. Certainly these changes are timely and important for students with disabilities. They are, however, extensions of historical requirements rather than paradigmatic shifts in the overall direction of the statute.

The more subtle and potentially deeper shifts in IDEA assessment practice reside in other parts of the statute and regulations. They *modify and extend* historical requirements in fundamental ways. Three major changes will be discussed here. The first foundational change stems from the use of a few, carefully chosen words in the section on full and individual assessment. Assessments are now required to contain "functional and developmental" information when students are being assessed for special education entitlement purposes. These terms apply to assessments for all disability conditions included in the law. What these changes mean in terms of practice shifts remain to be seen. Few if any states have fundamentally modified their special education processes based on this language change, so we can only speculate. However, given a read of the entire statute and regulations, it is clear that Congress expects that assessment procedures lend more information to the education process than historical diagnosis and placement information provided. In the context of problem solving, these requirements are met quite deliberately through the problem analysis phase of the process. Assessments are done that contribute to both administrative (i.e., entitlement and placement) and educational decisions (i.e., what and how to teach).

A second shift in assessment requirements is presented in the IEP section of the statute. Historically, IEPs were required to have long-term goals and *measurable objectives*. In IDEA 97, IEPs must contain *measurable long-term goals* with attendant benchmarks or short-term objectives. This shift subtly moves assessment attendant to the IEP process from a short-term measurement paradigm to a long-term measurement model (cf. Fuchs & Deno, 1991). Implications of this shift for practitioners are significant and well beyond the scope of this chapter. At a minimum, however, this change requires IEP teams to document student growth by more carefully selecting behaviors to measure over longer periods of time. Attendant measurement systems will need to have improved technical qualities and be sensitive to relatively small increments of student growth. This second subtle shift raises the bar with regard to another problem-solving decision: progress monitoring.

A third and most important shift in IDEA 97 assessment requirements is statutory language dealing with educational accountability. Part of this shift is embodied by the requirement to include students with disabilities in large-scale assessments. This change is only one small part of the increased accountability requirements. Historically, the special education system has been accountable for processes, procedures, and paperwork. Schools are now accountable for student learning. Students with disabilities now not only must be included in large-scale district assessments but their scores must also be included in the district's composite reporting to their community. Moreover, students with IEPs now must have their progress toward their special education goals monitored and reported out to their parents with the same frequency as students in general education. These changes move IDEA much closer to the outcomes criterion proposed by Reschly (1988). That is, the value of any human service profession, such as special education, ought to be determined by the benefits it confers to the recipients of the services. We now have the mandate to attend to student results, and we have emerging technologies that will allow us to do so. The question facing us all is, Does special education have the resources and the will to turn these new requirements into improved results for students?

SUMMARY

Just as the transition of other philosophically rooted disciplines to science was inevitable at a certain stage in their development, so too is the movement of school psychology toward problem solving. There is simply no other game in town that comprehensively addresses both the structural, procedural, and practice-based challenges that are so widespread in special education. Problem solving is here to stay. Indeed, with each reauthorization of the IDEA, increasing numbers of problem-solving concepts become codified as required practices. As we experience these changes, increasing numbers of broad-based, systemic problem-solving implementations are emerging across the country. In these systems, problem-solving processes are employed at two levels in the system. The first is the individual student level described in this chapter. At a second level, problem-solving concepts are implemented at a systems-level to structure and drive the change process. Not every aspect of problem solving can be implemented initially in any system. So problem-solving thought processes and structures are used to (a) help identify priority areas for change (discrepancies between what is desired and what is), (b) help analyze variables related to the situation, (c) help select components within the system, (d) help implement the changes with integrity, and (e) help monitor the effectiveness of the changes. In essence, the same thinking process can drive change in systems as drives change for students (Grimes & Tilly, 1996; Tilly & Grimes, 1998).

After more than 10 years of implementation of problem solving in Iowa, an uneasy though fair question must be addressed. So, how many problems have been solved? This question brings up a myriad of evaluation design issues, but the short answer is quite a few. Students with disabilities' problems are addressed earlier, more systematically, more collaboratively, and with a high degree of success. The proportion of problems solved is certainly not 100%, however, which leads to the quest for increasingly better solutions for student problems. Problem solving is not a panacea, nor a simple solution. It provides the structure and framework for implementation of current and emerging best practices in psychology and education. If an alternative system emerged that resulted in greater demonstrable benefit for students, we would adopt it. Until that time, however, problem solving remains a most thoroughly thought-through structure to deliver educational interventions to students. It takes time. It takes energy. It takes relearning on the part of nearly everyone. It also results in demonstrable benefits to large numbers of students, which is a foundational reason for school psychology.

Problem Solving as "Best Practice"

Stanley L. Deno
University of Minnesota

OVERVIEW

Successful functioning in any role requires a clear image of the primary purposes of that role. A cursory review of the current literature in school psychology reveals that clarity of purpose is lacking in the school psychologist role (Kramer and Epps, 1991). While the primary purpose may not be clear, the predominant activity of school psychologists is easy to identify. Assessment—with its related ignominious responsibility as gatekeeper for special programs—remains the most conspicuous activity of school psychologists. The problem with restricting the role of school psychologist to that of psychometrician is that many school psychologists have broader training and interests and are eager to make a broader contribution to child and family development. In the present chapter a case will be made that a broader and more satisfying role for school psychologists is that of data-based problem solver.

Fostering Human Development as the Purpose of Schooling

In developing a conception of school psychologists as problem solvers consider first the context within which they work. As participants in school environments, school psychologists are committed to the general purpose of schooling; that is, facilitating human development. This means, of course, that school psychologists will embrace the cognitive, affective, social, and physical developmental outcomes around which schools are organized. Within this framework, the problems to be solved by school psychologists are those generated out of the schools' efforts to promote growth and development.

INTERVENTION

If the purpose of schooling is to foster the development of children and youth, then we can identify the mechanism of schooling as intervention into "natural" (i.e., unschooled) development. The term "intervention" is appropriate in that society has vested educators with the responsibility to organize deliberate activities that affect the course of child development. Without those deliberate activities of schooling the developmental experiences of those students would certainly be markedly different. The term "intervention," then, can be used very broadly to refer to the processes of schooling. Society organizes the schools to redirect the developmental processes that would occur in their absence.

PROBLEMS

Just as the term intervention can be used broadly to refer to the mechanisms of schooling, the term "problem" may be used to refer to the question of how best to attain the specific outcomes of those interventions. Thus, when schools focus their activities on developing literacy and numeracy, the problems to be solved are how best to promote the development of reading, writing, and arithmetic. When schools seek to foster personal and social development, the problems to be solved are how best to promote the levels of development desired in these domains. When students take courses in physical education, the problems are how to best affect the physical development of children and youth. Societal priorities for the outcomes of schooling, then, establish the developmental problems that serve as the focus of intervention.

Given the perspective presented here, problem solving is not a term reserved for activities that focus only on atypical development. Instead, problem solving is defined as the approach to intervention rather than by a focus on failure or deviance. Problem solving is the effort to eliminate the difference between "what is" and "what should be" with respect to student development. Such a difference exists, for example, whenever we consider a student's current level of development relative to a desirable goal. Any discrepancy between where a student is currently functioning and how we might like that student to function at some point in the future automatically provides a focus for problem solving and can be adopted as the purpose of school psychology. Taking such a broad approach to problem solving is also useful because it avoids controversies surrounding a question of whether or not a problem "really" exists. Within such an inclusive definition, the school psychologist is in a position to work both proactively and reactively to facilitate normal development as well as to remediate delays.

The standards-based reform movement in American education is a good example of differing perceptions of the outcomes of schooling. While parents routinely express high levels of satisfaction with the schools their children attend, state legislatures are requiring high stakes testing due to their perception that the public schools are failing our children. Obviously, whether or not the developmental outcomes currently attained by American students are viewed as satisfactory depends upon the standards applied by the person making the judgment. Many of us have experienced situations where we viewed a child's development as being quite satisfactory where the child's parents who wanted more were quite unhappy.

Controversy over whether "real problems" exist can be reduced if we view our work from a developmental perspective where all children and youth are seen to move at an irregular pace along various continua. Any child's current level of performance in some developmental domain always will be the focus of interventions we design to effect whatever movement along those continua we specify, and the purpose of school psychology can be to determine how best to accomplish that movement. School psychologists who conceptualize their work in this way are problem solving whether or not someone identifies a child as developing "normally."

Typical Elements of Problem Solving

While a variety of different perspectives exist regarding the nature of problem solving, three basic elements—formulating the problem, generating and selecting potential solutions, and testing the selected alternatives—are common. The "IDEAL" problem-solving model articulated by Bransford and Stein (1984) illustrates these elements. In that model IDEAL is an acronym for the steps typically required in problem solving: *I*dentify the problem, *D*efine the problem, *E*xplore alternative solutions to the problem, *A*pply a solution, and *L*ook at the effects of that application. In their generic form, these elements can provide the basis for the interventions created by school psychologists.

Types of Interventions

The interventions organized by the schools can be grouped into two general types. The first group consists of the ordinary curricular and instructional experiences available to all children attending regular classrooms in their home schools. These common experiences are intended broadly to affect human development through a general set of experiences that are to be inclusive of all students. This general education program is not focused on the specific developmental needs of individual students and is assumed to benefit students who are typical in their development. A second, smaller group of interventions organized by the schools is specifically focused on the special developmental needs of students who are not developing typically. These special and compensatory intervention programs are not available to all students as are the general education interventions, and they are intended to be much more focused in character.

School psychologists, potentially, work as problem solvers in both general and special programs. In reality, however, the schools generally allocate school psychologist time to problem solving in support of students who are not developing typically. For that reason, the remainder of this chapter will focus on the problem-solving activities of the school psychologist within the context of special and compensatory programs.

The Role of Assessment in Problem Solving

The IDEAL model of problem solving includes the terms "identify" and "look at" (Bransford & Stein, 1984) to refer to the informal processes of sensing and perceiving aspects of the world that constitute the activities that school psychology refers to as "informal" assessment. Despite the fact that these activities are viewed as informal and natural elements of ordinary human problem solving, we should explicitly acknowledge the role played by these informal assessment activities in problem solving. To view the function of assessment as contributing to problem solving helps to develop the rationale for the heavy emphasis given to assessment procedures in school psychology.

Assessment and Measurement Defined

ASSESSMENT

In school psychology, assessment is generally defined as the process of information gathering for purposes of decision making. When conducting assessments, the information gathered can be qualitative or quantitative and verbal or numerical. Information is gathered through a variety of means—highly structured deliberate efforts involving intrusive test administration or informal and naturalistic observation. And, the information is used for a broad range of decisions in education—screening, classification, placement, and intervention evaluation. Narrative reports, anecdotal records, test scores, and coded observational data are all encompassed by the term "assessment." No matter what methods are used to gather information, the key element in assessment is neither the information gathered nor the procedures used, but the decision to be made. Similarly, whenever assessment is used effectively in problem solving, the focus must always be on the problem to be solved. This point is obvious, but it cannot be emphasized too strongly. Professionals who work in bureaucratic systems and are overworked easily become procedurally focused rather than problem focused in their work. That risk is particularly high for school psychologists who necessarily become involved in the paperwork required to provide due process protections to students referred for special education assessment.

MEASUREMENT

In general practice, the terms measurement and assessment are often used synonymously, and while they overlap, some consideration of their relationship is appropriate. Assessment is a broader term than measurement and is inclusive of the information gathering procedures denoted by the term measurement. Whereas assessment includes all types of information gathering and all types of information, measurement is limited to numerical description and representation of observations and, to the extent possible, scaling those observations. Observations designed to "measure" behavior are organized and structured either as tests where the testers set the occasion for behavior, or as observation systems that quantify behavior in natural settings. In either case, the purpose and outcome of measurement is numerical description. Another useful distinction between measurement and assessment is to identify the general purpose of assessment as "informing" and the special purpose of measurement as "clarifying." The increase in clarification produced through measurement occurs by using numerical scales designed to increase the sharpness or precision of the information that is provided. Despite deliberate efforts to increase clarification through quantification in information gathering, some argue that this increased precision is gained at the expense of qualities that cannot be represented numerically (Hesushius, 1991). Indeed, current advocates of "authentic performance assessment" (Darling-Hammond, Ancess, & Falk, 1995) generally eschew the use of conventional measurement approaches for making high stakes educational decisions.

DOCUMENTING IMPRESSIONS

Theories have existed for nearly 50 years that thought directed toward problem solving originates from experiencing cognitive conflict (Berlyne, 1965; Festinger, 1957). In such theories, cognitive conflict occurs when a person perceives a discrepancy between what they desire and what they experience. For professionals working in the schools, cognitive conflict often arises when a difference is perceived between what a student does and what the person would like the student to do. At such times, people respond to the conflict by thinking and behaving so as to reduce the sense of discomfort produce by that conflict. Festinger (1957) termed the process involved in reducing cognitive conflict "dissonance reduction."

If ordinary problem solving originates in the perceptions of the difference between what people want and what they get, then assessment can play a role by verifying or documenting the basis of those impressions. Measurement can be used to clarify the perception of difference between expectations and current reality. Initial impressions are certain to be implicit; therefore, assessment can help to make that experience explicit. For example, the perception that a student is having difficulty learning in school will be based on natural interactions and observations. That perception can be objectified through collecting data on the student's current level of performance and contrasting it with our expectations for that performance. The process of objectifying perceptions rather than simply relying on tests might help to explain the popularity of non-test–based approaches to assessment. Advocates of qualitative approaches, for example, might find naturalistic methods of assessment more appealing because they seem more open to authenticating the intuitive perceptions. Indeed, the term "authentic assessment," though prejudicial in its common usage, most likely underscores the desires of many to document sensations and impressions of broadly observed student capabilities.

CLARIFYING AND DEFINING DISCREPANCIES

A distinction often not made explicitly in problem-solving models is that between sensing and defining. While sensation is an intuitive process, definition is formal and explicit. The distinction can be clearly understood in the difference between the statements "I think something's wrong" and "I wonder what it is." While the former statement is a manifestation of the feeling of discomfort (i.e., "cognitive conflict"), the latter statement directs us to explicitly formulate the conditions that are producing this discomfort. A first step in reducing this cognitive conflict is to clarify and explicitly define the source of our discomfort. To do this requires that we identify the discrepancies observed in our environment.

When we are involved in enhancing human performance, the discrepancies of particular interest to us are those rooted in academic and social expectations. These expectations reveal themselves whenever concerns are expressed regarding a student's current functioning in a particular environment. In such instances, assessment for purposes of clarifying a discrepancy requires that information be collected to document both the current level of student performance and the level of performance desired by whomever is concerned. Careful reflection on this point reveals that a useful assessment of this discrepancy will require as much attention to assessing the standards of performance by those expressing concern (typically, teachers or parents, etc.) as to collecting data on the current level of student performance. Assessing those standards will, of course, require diplomatic and sensitive probing of both subjective and objective dimensions of those standards. For that reason, school psychologists must consider not only the objective dimensions of behavior, such as frequency, magnitude, or latency, but also subjective assessment procedures designed to appraise the perceived importance of a discrepancy.

To illustrate how assessments are conducted to clarify and document the existence of a problem, consider the example of "work completion." To assess a student's current level of work completion we might collect observational data on the percentage of current work being completed by that student during 1 week and find the student's completing between 60% and 70% of that work. We might then explore carefully with the teacher to determine what level of work completion is acceptable and find that the teacher expects "virtually all," say, 90–100%, of the work to be completed. By collecting this information we have established a quantitative difference in performance of 30% between what the teacher wants and what the teacher is getting from this student. At this point, however, we do not know how important that difference is to the teacher. For some teachers a difference as small as 15% between what they desire and what they get is extremely important; while, for others, a difference of 30% is viewed as only moderately important. This distinction between the magnitude of a problem and its perceived importance is the difference between quantification and values. At this point, then, the assessment process must address the even more subjective issue of the significance or "social validity" of the problem, and could require involvement of other significant adults in the student's life and an extension of data collection to obtaining normative peer data.

GENERATING ALTERNATIVES

Once a problem has been identified and established as socially valid, assessments are conducted to aid in selecting from among alternative intervention hypotheses. In conventional terms, some effort is made to differentially diagnose and prescribe a "treatment" that may resolve the problem. Conducting assessments for purposes of developing alternative solutions to a problem, while widely undertaken, is still an uncertain technology. Assessment of this type is organized on the assumption that information from student performance will direct us to interventions that are more effective. The reality is, however, the technology for diagnostic assessment is neither sufficiently reliable nor valid for accomplishing this task. The lack of validated diagnostic assessment procedures is not for generating limited to more traditional differential diagnostic procedures based on standardized ability tests. Research is, as yet, unavailable on the diagnostic utility of currently available observation systems and rating scales that have been designed to describe classroom ecologies. The same can be said for the use of the popular efforts to assess "learning styles" and develop strategies consistent with those styles (Stahl, 1999). And, finally, while a subskill assessment approach makes sense to some, it has been widely criticized as reductionist by those who take a constructivist approach to education (Hesushius, 1991). Special education generally relies on mastery learning approaches built on task analysis and criterion referenced testing. Nevertheless, we might best be advised to expect relatively low-cost benefit ratios from the use of any particular approach to assessment in generating solutions to problems. At this point in the problem-solving process, school psychologists serve their clients better by being thoroughly knowledgeable of broad-based, field-tested intervention research than they do through speculating from currently unsupported diagnostic testing. For example, a thorough knowledge of the recommendations from the National Reading Panel (2000) regarding what is currently known about developing reading proficiency will enable school psychologists to offer more in the way of evidence-based interventions for solving reading problems than will unsupportable speculations from assessment data. Teachers are eager to learn of alternative approaches when current practice is not working. Many school psychologists have learned to play a key role in problem solving through generating alternative solutions in addition to sharpening problem definition through assessment.

DOCUMENTING INTERVENTIONS

It may seem surprising to consider the role of assessment in documenting that interventions are occurring as intended. However, the experience of school-based researchers has established the importance of determining "treatment fidelity" when exploring treatment effects. It is equally clear that we need to assure that problem-solution alternatives have been implemented and are operating with sufficient intensity before we attempt to evaluate their effects. Many of us have had the experience of working as collaborative consultants to identify and plan what seemed to be reasonable potent interventions for solving a problem only to find upon subsequent review that those interventions were only partially or incompletely implemented. In such cases we may not have solved the problem as intended and neither have we established whether the problem could be solved if the intervention had been implemented. If we are to actually test the effectiveness of solution alternatives, then every effort will be made to document that the alternative has been fully and completely implemented and that the student experiences that intervention. It is interesting to wonder how many potentially successful solution alternatives have been discarded because the intervention was never actually tested because of insufficient implementation.

FORMATIVELY EVALUATING SOLUTIONS

In models of evaluation, a distinction is typically made between formative and summative evaluation (Scriven, 1967). The evaluation of a program during its implementation for the purpose of increasing its success is formative evaluation. Summative evaluation, on the other hand, occurs upon completion of a program for the purpose of determining whether or not the program has achieved its goals. The purpose of formative evaluation is to determine the apparent success of an intervention during its implementation so that it can be modified or changed to increase the likelihood that intended results will be achieved. The distinction between formative and summative evaluation is useful within a problem-solving framework because it emphasizes the key role that assessment can play during implementation in informing decisions about how a program can be shaped to increase the likelihood of problem solution.

In the IDEAL problems-solving model, formative evaluation occurs when "looking at" the results of applying a solution reveal that the solution has not worked and exploration for an alternative approach to solving the problem must proceed. The advice, "If at first you don't succeed, try, try again" well captures the essence of both the IDEAL model and the purpose of formative evaluation. Not surprisingly, evidence exists that using formative evaluation of interventions increases their success (Fuchs and Fuchs,1986). Indeed an argument can be made that along with conducting assessment to initially clarify the nature of a problem, assessment as a basis for formative evaluation contributes most significantly to problem solution. For that reason in remaining sections of this chapter considerable attention will be given to the school psychologist's role in formative evaluation of intervention attempts.

DETERMINING SUCCESS

Assessment contributes to clarifying and determining problem solution in essentially the same way that it contributes to initial clarification and definition of the problem. In evaluating program success the same assessment procedures that were used initially to clarify the discrepancy are used to establish whether that discrepancy continues or has now been eliminated. To do this requires the same degree of thoroughness in determining both the degree and importance of any difference between what is desired and what is actually occurring. Following from our earlier example of work completion, this means that we must once again determine the difference in percentage between the student's current level of work completion and the level specified by the teacher. In addition, the teacher's perception of the importance of that difference must be reassessed. In the best of all worlds, no difference will exist. Often, however, we may find that the teacher's performance standards or values regarding the importance of a difference may have changed even while the student's level of work completion increased. Although we may view this as a hurdle in our efforts to solve the problem, evidence exists that "goal ambitiousness" and goal raising by teachers are important factors in increasing the level of achievement attained by students (Fuchs, Fuchs, and Deno, 1985). Indeed, the purpose of school psychology presented at the outset of this chapter was continuous solving of human development problems. While the implication of problems solving is that we may exit a situation when "the" problem has been solved, the ambitions of the teacher (and our own, for that matter) to optimize development often means that "exiting" is a momentary vacation from work rather than a condition of our employment.

Solving the Problems Called Handicaps

In ideal circumstances school psychologists are free to act on the complete range of developmental problems that are encompassed by the work of the schools. In reality, however, most school psychologists are constrained to give priority to problems associated with disabilities. Within the problem-solving framework presented in this chapter, those problems experienced by people with disabilities are called "handicaps." What follows is a set of distinctions among the terms "handicap," "disability," and "impairment" that are useful within this problem solving framework.

DISABILITIES AND HANDICAPS

In 1976, P.L. 94-142 was passed as the Education of the Handicapped Act (EHA). When the revision of that law was passed almost 15 years later as P.L. 101-476, the law became the Individuals with Disabilities Education Act (IDEA). That change from using the term "handicap" to the term "disability" occurred not only in the title, but also throughout the text. The change in terminology could easily be dismissed as an attempt to keep up with the current jargon in special education—that this was simply a cosmetic change having more to do with a shift in form rather than substance. Clearly, however, the people with disabilities and their advocates did not view the change as trivial. Indeed, people with disabilities see as central to their concerns the need for society to understand the distinction between the concepts represented by the terms "handicap" and "disability." We need to reflect on that distinction and its importance in problem solving.

HANDICAPS AS PROBLEMS

A useful beginning to defining "disabilities" and "handicaps" within problem solving is to classify as handicaps the particular set of problems that the schools are attempting to solve through special education. From this perspective, handicaps are viewed as the difference between what someone does (or can do) in a particular situation and what is required of that person to be successful in meeting the demands of the situation. In common experience, a person who can use a wheelchair to move about in the environment is not handicapped until required to gain access to a building that has only steps at its points of entry. In a similar fashion, someone who has low visual acuity is handicapped when the option for gaining necessary information is to see words projected on a screen or written on a chalkboard. Finally, a high school student who cannot read and must do so to complete daily assignments is handicapped. What is clear in each of these examples is that a discrepancy exists between what the individual can do and what the task demands to be successful. What should further be made clear at this point is that the term "discrepancy" used in the present problem-solving model differs from its use in the context of common definitions of learning disabilities. In the definition of learning disabilities the term "discrepancy" refers to a difference within the individual between an ability test score and an achievement test score. In the problem-solving model presented here, the term "discrepancy" refers to a difference outside the individual—the difference between the level of performance required to meet environmental demands and the level of performance emitted by the individual.

DISABILITIES AS INDIVIDUAL CHARACTERISTICS

Whereas handicaps are conditions created by the relationship between what the individual can do and what must be done to succeed at a particular task, disabilities are conditions of the individual. In each of the examples provided above the "disability" is that characteristic of the individual's performance that does not match the demands of the environment in that situation. The performance characteristic of an individual is commonly termed a "disability" when the performance is substantially different from the typical performance of one's peer group. Given this perspective, disabilities are defined by the normative differences in performance while handicaps are defined by the mismatch between the person's ability and the minimum standards required for successful task completion in a particular situation.

Another important distinction between disabilities and handicaps is the degree to which the existence of the condition can be altered by changing the environment. As was illustrated in the foregoing examples, changing the environmental demands could eliminate each handicap. If wheelchair access to a building is created, the handicap no longer exists. If large print paper copy is provided at the student's desk, then the notetaking handicap no longer exists. If the information required to complete daily work assignments is made available through audiotapes, then no reading handicap exists. In each of these examples altering task demands can eliminate the handicap. The same cannot be said for each of the disabilities. In all three cases, the individual's level of performance (i.e., walking, seeing, and reading) is unaltered by the modifications made to enable successful task completion; nor could anything be done to immediately alter the individual's capability. Normatively defined disabilities change only when the individual's performance capability changes or the performance of the norm group changes. As also is evident from the examples, the handicap is immediately eliminated when the environment is modified in such a way that the requirements are congruent with the person's performance capabilities.

The role that norms have played in defining disabilities has been clear for quite some time. What has been less clear is the role that society plays in creating the handicapping conditions. Even in acting as a caring society we have tended to view handicaps as problems possessed by the individual with which we might help them to cope. By changing the language of the law from handicap to disability, advocates for people with disabilities have attempted to influence us to think more completely and carefully about our role and responsibility in creating handicaps. They question the morality of a society that creates requirements for task success based only on the capabilities of the majority while ignoring the capabilities of people with disabilities. Beyond that they question the assumption that those who cannot fulfill requirements based on the standards of the majority must bear full responsibility for their lack of success.

The handicapping conditions created by the schools are many and not always easily identified. Many students struggle to read text but must read extensively to earn top grades. In a general sense, all students with reading deficiencies are handicapped when the difficulty level of classroom reading requirements set by their teachers exceeds their current reading ability. The same can be said for students who do not write well or compute fluently. Disability advocates have done all of us a service by heightening our awareness that the common standards for performance that we create in the schools contribute as much to creating the problems to be solved as performance characteristics of the students who cannot meet those standards. Having been made aware of this issue, the question that we must keep foremost in our setting of standards is whether they are appropriate for all students or only for the majority.

A third, important, concept related to disabilities and handicaps is the concept of impairment. In the present discussion, the term "impairment" is used to refer to a biological dysfunction or anomaly. Impairments may, or may not, be related to the level of an individual's ability or performance. Spinal nerve damage is an impairment that can affect the level of an individual's ability to walk. Similarly, damage to the optic nerve or the retina may be a biological condition underlying or affecting visual perception, and damage to auditory mechanisms may result in lowering an individual's ability to discriminate speech sounds. Historically, our legislatures have written laws on the assumption that disabilities in performance were caused by specific and identifiable impairments. Indeed, many disability advocates argue that all disability conditions funded through federal law should be clearly based in biological anomaly. This line of reasoning has proved particularly problematic for conditions such as learning disability, emotional disturbance, and mild mental disabilities where impairments are difficult to identify. The need to identify impairment is served by current research to map the brains of people who are "dyslexic" using advanced electronic techniques such as PEP scans and magnetic resonance imaging. The hope is that such research will not only result in the development of appropriate treatments, but also will establish that impairment is at the basis of the disability. The fundamental belief undergirding this approach is that special education resource expenditures will be justified if anomalies can be identified in the brains of individuals who have difficulty learning to read. With respect to serious emotional disturbance, however, it has been thus far both conceptually and procedurally impossible to identify a biological basis for the disability.

While fairly clear connections can be drawn between some biological conditions and specific levels of competence, the relationship between the biological condition and the level of functional performance obtained by the individual is typically not direct and is always very complex. When central nervous system trauma occurs through closed head brain injury or spinal cord injuries, the degree to which an individual will lose or recover functioning associated with those injuries is difficult to predict. While this is due in part to difficulty in estimating the degree of healing or damage, it is also because the central nervous system is able to adapt in ways that produce improved functioning even when impairments exist. Considerable evidence exists that when the dominant cerebral hemisphere is traumatized the less dominant hemisphere will take over some of the functions normally associated with the dominant hemisphere. The same difficulty exists when attempting to estimate the performance consequences of sensory impairments. Audiometric and opthamological examination cannot fully ascertain the degree of useful hearing or vision. Legal classifications of blindness that are based solely on sensory acuity often result in the apparently contradictory situation where someone who is "blind" can read ordinary print. Further, while some students who are classified as hard-of-hearing can complete their schooling without the use of technological aids or compensatory programs, others have such great difficulty developing oral language skills that they are more likely to succeed in a residential school where communication occurs through American Sign Language.

In summary, in the problem-solving framework provided here, disabilities are conditions of the individual that refer to the fact that their level of competence, performance, or ability to do something is consistently and significantly lower than that of their peers. In contrast, impairments are biological conditions of the individual believed to underlie an individual's apparently unalterable disability. Handicaps are conditions that exist when successful functioning in an environment requires a level of ability beyond that possessed by the person. A neat, simplistic formulation of the relationship among these three terms is that biological impairments produce disabilities that often result in the occurrence of handicaps. While many relatively simple and straightforward examples of this formulation exist, the functional relationships among these three terms are typically very difficult to establish.

SEVERITY OF DISABILITY

No discussion of disabilities and handicaps is complete without consideration of the degree or severity of these conditions. Earlier in this chapter the magnitude of a problem to be solved was described as having two parameters: its measured or objective dimension and its reported or expressed values dimension. The same two parameters apply to the concepts of disability and handicap. The objective or measured severity of a disability refers to the scaled difference between the individual's performance on a particular task and the typical performance of the peer group.

If we present students with text passages from the local newspaper and ask them to read those passages aloud for a minute, they will differ with respect to the number of words they read correctly and incorrectly. If we do this for a representative sample of students at the same age, we will find that the scores will be distributed from relatively lower to higher levels of accurate production. Further, the distribution of these scores will approximate normality, and we will be able to consider the scores as points along a continuum. The differences in individual performance on this particular task are interpreted to represent differences in underlying reading ability and are considered to be an objective measure scaling of that ability. Although some students consistently obtain a very low score on this task, the low score, alone, does not establish the existence of a disability. To establish a particular level of performance as disabled requires that standards be set for what is considered to be "normal" performance. Performance standards are external to the task itself; that is, nothing about the task itself establishes normality or importance. The number of words read correctly and incorrectly is only a fact about performance until a framework for interpretation is created. The most common standards for interpretation applied to human performance, of course, are normative. Teachers usually acquire informal normative standards through working with their students. These informal standards account for the fact that teachers judge some students to be "able" when performing a particular task because they are performing similarly to students of comparable age. Other students are considered to be "exceptional" if they perform much better or worse. In the present context, the students who perform well below the teacher's standards for normal performance are thought to be less able or, possibly, disabled. Since teachers vary in their experience and their personal standards, efforts are made to standardize the criteria by which performance is to be classified as disabled. Indeed, to be able to establish consistent criteria for judging performance through the use of norms is one of the most important contributions of standardized tests to education.

While norms provide a useful basis for objectively discriminating between levels of performance, and thereby help to establish degrees of ability and disability, they are not sufficient to establish the social significance of low levels of performance on a task. The value of performance on a particular task derives from the need for competence at that task within the culture. For example, being able to read words with the same speed and accuracy as one's peers only becomes important when the personal and social consequences of performance on that task are important. Thus, performing more than two standard deviations below the mean at "singing in tune" is objectively quantifiable, but it is not identified as a severe disability in our American culture. The same cannot be said for similarly low performance in reading and writing.

SEVERITY OF HANDICAP

Like the severity of disabilities, the severity of handicaps is defined both objectively and subjectively. The measurable and the expressed value dimensions of handicaps are not identical to those of disabilities, however. The performance aspect of a handicap may be measured in the same way as a disability; however, the standard for successful performance may be established quite differently. Recalling that disabilities are most often defined on the basis of performance relative to norms, the performance standards or requirements that established the existence of a handicap may be established independently from current norms. This distinction is well illustrated whenever the media claim that a crisis exists with respect to the performance of American students in math and science. If we apply only normative standards to evaluating the performance of students in the United States we could argue that nearly 85% of the students will be performing within the normal range (i.e., at a level equal to, or greater than, one standard deviation below the mean). Despite this, U.S. policy makers are urged to view normative performance as insufficient and to set a higher standard. If we were to apply only normative standards to evaluating the performance of students in the United States we could argue that nearly 85% of the students will be performing within the "normal" range (i.e., at a level equal to, or greater than, one standard deviation below the mean). Despite this, U.S. policy makers are urged to view normative performance as insufficient and to set a higher standard. As the argument goes, setting "world class" standards will enable American students to compete in the world marketplace. While an empirical basis typically does not exist when higher standards are set, it is assumed that higher standards are both possible and desirable. Under any circumstances, the standards that are set are clearly not normative. More common examples of how non-normative standards are imposed to create handicapping conditions can be found in the examples of parenting. A parent may establish that a son or daughter must attain a particular grade point average to drive the car. The son or daughter may already be performing "normally," but the parent may desire or value a higher standard of academic success. This standard is derived from the values of the parent without particular reference to normative grades. Without arguing the merits of setting higher standards, it is clear from these examples that, unlike disabilities, the severity of any handicap will be determined by something other than deviation from typical performance.

CONSEQUENCES AND HANDICAPS

Handicaps can also be distinguished from disabilities because handicaps inevitably are associated with contingent consequences. What this will mean for the individual is that the outcomes will differ when performance is, or is not, consistent with the environmental demands. In the earlier illustration of wheelchair accessibility to a building, the goal of building entry (for attending classes or going to work, perhaps) is either achieved or denied. Thus, not only does loss of access to the building occur when the environmental conditions are beyond the individual's level of performance, but the loss of rewards associated with employment or attending classes in that building also occurs. The parent who set the higher grades standard for using the car has created the incentive consequences related to student performance. If the parent establishes a grade criterion that consistently exceeds the student's capability, then failure will result in loss of an important incentive for the son or daughter. Those low performing readers described earlier who cannot read their subject matter texts well enough to do their daily work are not only disabled but are handicapped. The handicap exists not simply because the requisite performance standards exceed their current capability, but also because in failing to attain those standards they will not achieve the desired grade outcomes. The severity of a handicap, then, is based both on the magnitude of the discrepancy between what the individual can do and what the task requires, and the magnitude of the incentive consequences associated with that discrepancy.

RELATIONSHIP OF HANDICAPS TO PROBLEM SOLVING

It should be clear from the foregoing discussions that the definition of "handicap" parallels the definition of "problem" developed at the outset. Problems are defined as the difference between the performance we want in a particular situation and the performance we get in that situation. Handicaps are a particular type of problem where we create environmental demands that exceed a person's current capabilities and the associated incentives for meeting those demands. Certainly, not all handicaps are treated equally within public policy. In particular, the handicapping conditions addressed through public law and special education are those we create by imposing conventional standards for performance on individuals whose performance in that area is disabled. Public law mandates that the problems of this type (i.e., handicaps for people with disabilities) be solved through accommodations within school and community settings.

BEST PRACTICES IN SOLVING HANDICAPS

Identifying and Defining the Problem

As with problem solving in general, solving the problems called handicaps requires cycling through the process of identification, definition, exploration of alternative solutions, implementation of selected solutions, and evaluation of the effects.

PROBLEM DEFINITION: THE KEY TO SUCCESS

Perhaps the most significant contribution that school psychologists can make to solve handicap problems is their collaboration with others to clearly and explicitly define the problem to be solved. This collaboration requires skill in working sensitively with others who have either created, or bear responsibility for meeting, the environmental demands that define the handicapping conditions. As noted earlier, clarity and precision in problem identification and definition are essential to successful problem solving. School psychologists are (or should be) uniquely capable of increasing clarity and precision by applying their knowledge of assessment. In this first step of problem solving, school psychologists can significantly contribute by helping to develop and select assessment procedures that aid in precisely defining both the individual's current level of ability and the environmental demands in excess of that ability.

School psychologists collaborating to clarify existing discrepancies must be particularly sensitive to the values at the heart of the performance standards. No assessment procedure alone will be sufficient to establish the existence of a handicap. They must emphasize that, at best, standardized tests scores reveal the performance differences that aid in defining disabilities rather than handicaps. Alone, these scores do not prove that a problem exists that must be solved. Differences within the norm group on a particular test are meaningless until the values context associated with the performance on that test is clearly explicated and agreed upon. As we shall see later, this issue also becomes important in attempting to establish both the need for special education and the annual goals for an Individualized Education Plan.

CULTURAL IMPERATIVES

When attempting to collaborate with others in examining the value context surrounding handicaps, the idea of cultural imperatives is useful for identifying the handicaps that are sufficiently important to be addressed by a society and those that are not. For our purposes here, cultural imperatives are those types of performance so valued by a society that school standards are set for that performance and resources are allocated to overcome developmental discrepancies in those areas. In America, for example, we allocate considerable resources to support learning to read, write, and compute. The high priority placed on competence in these domains is easy to infer simply by examining both the daily schedules of lessons and the curricula of the schools. Not only do the learning activities in these domains occupy prime time in the school day, but when students have difficulty in learning these tasks additional resources are used to develop remedial and compensatory programs to assure literacy and numeracy. Further, both federal and state policy initiatives have been created to assure that American students excel in these areas.

Cultural imperatives are easily understood when contrasted with cultural electives. Cultural electives are those abilities that, while valued by society, are given lower priority for resources than cultural imperatives. Musical abilities are good examples of a cultural elective. Students are often given the opportunity in school to develop some degree of competence in music; however, relatively small amounts of time in the schedule are provided and, when resources are short, music is among the first to be cut from the school curriculum. Indeed, while we may think of someone as not very musically inclined, we are unlikely to refer to the individual as "musically disabled" or handicapped. While a performance discrepancy in music may be as large as it is in reading, no additional societal resources will be forthcoming to overcome that discrepancy. Clearly, it is the difference in value vested in these activities within the culture that establishes that one disability is important and the other is not. Further, the magnitude of the incentive consequences associated with culturally elective handicaps is typically very small.

SITUATIONAL HANDICAPS AND CHRONIC DISABILITIES

A second set of concepts that is useful in making problem priority decisions is the distinction between situational handicaps and chronic disabilities. In the foregoing discussion we can see that handicaps might exist in any situation and for only a moment in time. That is because, as members of society, we create handicaps whenever we establish standards for performance that someone cannot meet. As pointed out earlier, handicaps are often created for people whose abilities are normal. Distinct from these "situational handicaps" are "chronic disabilities." Chronic disabilities are trans-situational and enduring. An otherwise typical student, or group of students, can have great difficulty meeting the performance demands of a teacher because the teacher's work demands are not appropriate to their level of skill. This problem is quite different from the conditions for a student who has serious difficulty in learning to read for several years, regardless of the teacher, and is routinely handicapped in school. In the former case the handicap is situational, while in the latter case the disability is chronic. In both cases discrepancies exist between what the individual can do and what the individual must do in order to succeed, but in the case of situational handicaps the problems are relatively temporary or local. Students with chronic disabilities encounter handicapping conditions where they must endure the consequences of failing to meet socio-cultural demands.

The distinction between situational handicaps and chronic disabilities is fairly obvious. At the same time, keeping the distinction in the forefront preempts questions regarding the priority that must be given to different discrepancies when selecting problems. Ultimately, the value system that underlies resource allocation and the rules related to those values would determine the priority among problems to be solved. As will be discussed later, however, the funding provided for solving special education problems is intended to assist those people whose disabilities are chronic rather than those with situational handicaps. This will mean that school psychologists will have to develop assessment procedures that can aid in distinguishing between problems that are situational and those that define the individual as disabled. As before, norms are useful tools in making this judgment because they emphasize individual differences in ability rather than failure to meet societal standards.

PROBLEMS AS RELATIONAL

A point often overlooked when defining and selecting problems as differences in expected and actual performance is that problems do not exist within the individual. This point was made earlier in distinguishing the use of the term "discrepancy" in the problem-solving model presented here and the common use of the term "discrepancy" when defining learning disabilities. In the model presented here, problems are defined by the discrepancy between an individual's performance and the level of performance that must be attained in order for the individual to be successful in attaining the associated incentive. At the same time it is important to point out that problems do not reside in the standard or level of performance that is desired. Using the discrepancy model clarifies that the problem is relational—that it resides in the relationship between individual performance and environmental demands. A problem may well exist when a student's reading skill is insufficient to accurately complete daily work assignments. To attribute the problem to the student's lack of reading skill or to the standards of performance set by the teacher is neither necessary nor helpful in problem identification and definition. Sensitivity to this issue helps to avoid blaming the victim—either the student or the teacher.

PROBLEM OWNERSHIP

While defining problems relationally helps to avoid concluding that someone *is* a problem, it is useful to identify who *owns* a problem. Ownership of a problem can be determined by identifying those individuals who view a performance discrepancy as being important and who are initiating action to solve the problem. As we identify problem ownership, we need to be mindful that problem owners are not only those who have established performance standards that a student cannot meet but also those who share a concern when a particular discrepancy exists. For example, a classroom teacher may be relatively unconcerned when a particular student cannot do daily assignments accurately, believing that low ability makes this inevitable. Likewise, the students may have come to accept failure as a part of the student's life. Parents, however, may be deeply concerned and may press the school for adaptations in their children's program. In such cases it is neither the parent's performance nor the daily work standards that define the problem, but the fact that the parents initiate action to solve the problem means that they are the owners of the problem. To paraphrase a well-known expression, "problems exist in the eye of the beholder." Once this is understood, it becomes clear that it is the owner of the problem whose desires and concerns must be made explicit to clearly identify and define a discrepancy and to establish its importance. Practically speaking, teachers and parents own most common school problems. They are most often expressing concern and taking action. Although it is tempting to identify the students as owning the problems, this typically is not the case.

DEFINING DISCREPANCIES QUANTITATIVELY

When a teacher uses language to express a concern over a performance discrepancy, the terms used are typically qualitative rather than quantitative. Thus, for example, a teacher might express concern by saying that a student is having "difficulty in reading"; and, when asked for more details, might say that the student is "unable to complete his independent work accurately." In attempting to clarify this problem we are confronted with the fact that the teacher's initial statement implies that the student has a skill deficiency in reading while the second statement points to a different type of performance; that is, "doing work accurately." While discrepancies may exist both in reading skill and work completion, and while failure to complete work accurately may be due to a reading disability, assessment of a difference between what the teacher wants and what the student does requires scaling performance along the same dimension. Thus, the student's "reading difficulty" needs to be operationalized, and the teacher's expectations need to be expressed in the language of that operationalization. In this case, careful probing may yield specific information regarding the reading book or books that are being used for instruction and the level of reading skill that is necessary to performing acceptably in those reading materials. Further exploration might result in finding that the teacher expects the student to be able to read from a fourth-grade literature book with approximately the same speed and accuracy as the average student in the class. The quantitative difference between the teacher's performance expectation and the student's actual performance in fourth-grade literature could then be obtained by using the Curriculum-Based Measurement (CBM) (Deno, 1985) approach to scaling reading differences. Using CBM involves comparing the student's performance to a normative sample of the class to determine the difference in the number of words read correctly by the peer sample and the target student. The result is a direct representation of the reading discrepancy along the same quantitative dimension—number of words read correctly in 1 minute. If, instead, the teacher seeks to define the problem in terms of work completion, an observational approach to assessing the discrepancy in terms of percentage of work completed could be accomplished (Deno, 1980).

Skill development problems, by definition, are discrepancies where the teacher's performance expectations exceed the student's level of performance. At the same time, this does not mean that the discrepancy always is one where the student's performance is lower than the performance the teacher desires. Behaviors that are deemed inappropriate or incorrect often occur at a level higher than that desired by the teacher. These "intrusive" behaviors include such things as high error rates in reading, spelling, and computing. They also include high levels of social behaviors like hitting, making noise, or being out of an assigned place. Whether the performance discrepancy is one where the actual performance is perceived to be too high or too low relative to the teacher's standards will not alter the basic utility of defining the problem in terms of quantitative rather than qualitative difference.

In closing this discussion of problem identification and definition, it is useful to once more emphasize that the key to successful problem solving is careful identification and definition of the problem. When problem-solving efforts are mobilized, available resources will move to the specified problem. Inaccurate or inappropriate problem selection will mean that the resources will be mobilized to solve the wrong problem. Unfortunately, after implementing a problem solution it is all too common to find that the owner of the problem expresses dissatisfaction with the results, not because the intervention plan has failed but because it has been focused on the wrong problem. In such cases the owner of the problem continues to be concerned because the discrepancy that had been eliminated was not the essence of the problem owner's concern. To avoid this outcome, we must be careful not to require teachers to define discrepancies in our preferred terms. The CBM approach described briefly above has proved useful to defining reading problems. That approach uses discrepancies in the speed and accuracy of a student reading from fourth-grade literature. We must be mindful that in using this approach to assessment we may be overlooking a problem of higher priority to the teacher. In the previous example, the discrepancy between the work completion rates of the student and the teacher's desired level of work completion may be of greater concern to that teacher. While we may be more interested in focusing on reading skill problems, the teacher may place higher value on developing good work habits. In such a case we might solve our preferred problem, but not that of the teacher.

Developing and Selecting Alternative Solutions

Once problems have been carefully defined it is possible to proceed to generating alternative plausible solutions for reducing the discrepancy. Since most school-based performance problems involve skill discrepancies, it is common to assume that developing student skills best solves most problems. Indeed, improving skill development is the goal of school programs. Nevertheless, we should remember that problems can also be solved by adjusting performance requirements in line with individual student capability. Particularly in the case of those problems called handicaps, changing performance is always more difficult than altering the environmental conditions necessary for success.

Discussions of whether to seek problem solution through changing performance or adjusting requirements are fraught with potential controversy and must be handled carefully. In most instances this will mean that the owners of a problem must become engaged in a constructive discussion of the relative benefits and costs likely to be incurred through modifying the performance or changing the environmental demands. Central to developing and selecting problem-solution alternatives should be the idea that discrepancies can be reduced by alterations in the performance, alterations in the task requirements, or by alterations in both the performance and the requirements for success. Within a problem-solving framework, a problem is eliminated when the owner no longer deems a discrepancy to be important. Either adjusting task demands to meet current student capabilities or moving performance standards to be congruent with current performance results in problem solution. As problem solvers, eliminating the discrepancy through either approach provides us with some satisfaction. At the same time, our professional responsibilities as school psychologists requires us to consider the moral obligations associated with the long-term consequences of a particular solution for the student. If lowering standards for performance solves the immediate problem, it might not be helpful to the student in the long run. This issue, of course, relates to the phenomenon of "goal ambitiousness" discussed earlier in this chapter.

DIAGNOSIS: AN UNDEVELOPED TECHNOLOGY

When a decision is made to solve a problem by improving student performance rather than by adjusting task demands, school psychologists are often called upon to conduct testing for the purpose of diagnosis. The intended outcome of diagnostic testing is, of course, a plausible explanation for the student's performance and some recommendations for intervention. In the case of chronic disabilities the diagnostic question focuses on why students are performing at a level significantly lower than their age norms and what techniques should be used to address the performance problems.

Despite the widespread use of diagnostic procedure, it is important to realize that, in the language of cognitive psychology, problems are "situated"; that is, they are defined by the specific circumstances in which they exist. Since problems are situated, their solutions also are situated. The situated nature of problems and their solutions means that success in problem solving increases with increased specificity of our knowledge concerning a problem. In most cases problems are so specifically situated that generic diagnosis is virtually impossible. The problem of situation specificity in diagnosis may well be why a reliable and valid technology of differential diagnosis and prescriptive treatment has never developed (Watkins, 2000; Deno, 1990; Snow, 1989; Arter & Jenkins, 1979). Unfortunately, a popular literature exists that learning problems can be overcome through greater attention to individual differences in "learning styles" (Snider, 1992), and school psychologists are too often cajoled into "going beyond the data" when meeting with others to solve problems.

PROBLEM SOLVING AS EXPERIMENTING

More than 30 years ago, Donald Campbell (1969) advised us in his presidential address to the American Psychological Association that we should treat "reforms as experiments." His thesis was that, since the outcomes of new or renewed programs were always unpredictable, we need to recognize that implementing them was a hypothesis to be tested. A similar view of problem solving can be extended to work in the schools. When we introduce changes in programs we need to be public that the effects of those changes are uncertain. For that reason, we must collect data in such a manner that the effects of program changes can be determined. As problem solvers, taking a hypothesis-testing approach enables us to avoid being trapped into the position that the changes we are proposing will certainly be effective. Psychological knowledge, at best, can only help us to estimate probabilities. Like the National Safety Council's predictions regarding the number of people who will be fatally injured in auto accidents during a holiday weekend, our generalizations about the effectiveness of programs are more accurate for groups than they are for individuals. Knowing that an intervention strategy has had a 50% success rate in influencing student behavior may help us to increase the chance of selecting a successful strategy, but we still cannot be very sure that the intervention will be effective in solving a particular problem. In our efforts to solve problems through modifying student programs we should avoid being trapped into acting as if we know with certainty that a particular intervention will solve a specific problem. We would be wise to encourage others to view our proposed solutions as operational hypotheses that can, and should, be empirically tested. By doing so we encourage the development of assessment procedures that are problem specific and produce data that aid us in evaluating our problem-solving efforts.

Progress Evaluation

A critical issue that arises when we seek to approach interventions in student programs as experiments is the method to be used for empirically testing the effects of those interventions. The most common method used in education to evaluate programs is an arrangement where students are pre-tested prior to implementing a program change and then post-tested at program completion. Pre-testing is used to create a snapshot picture of the initial difference between actual and expected performance, and post-testing provides a similar static picture at the completion of an intervention that aids in determining whether or not the discrepancy still exists. While pre-post–test arrangements make an important contribution to evaluating our problem-solving success, it actually constitutes a weak set of conditions for making valid judgments about the effectiveness of interventions (Campbell and Stanley, 1963). Recent developments in procedures that can be used for monitoring individual student progress now provide an alternative to pre-post–testing arrangements.

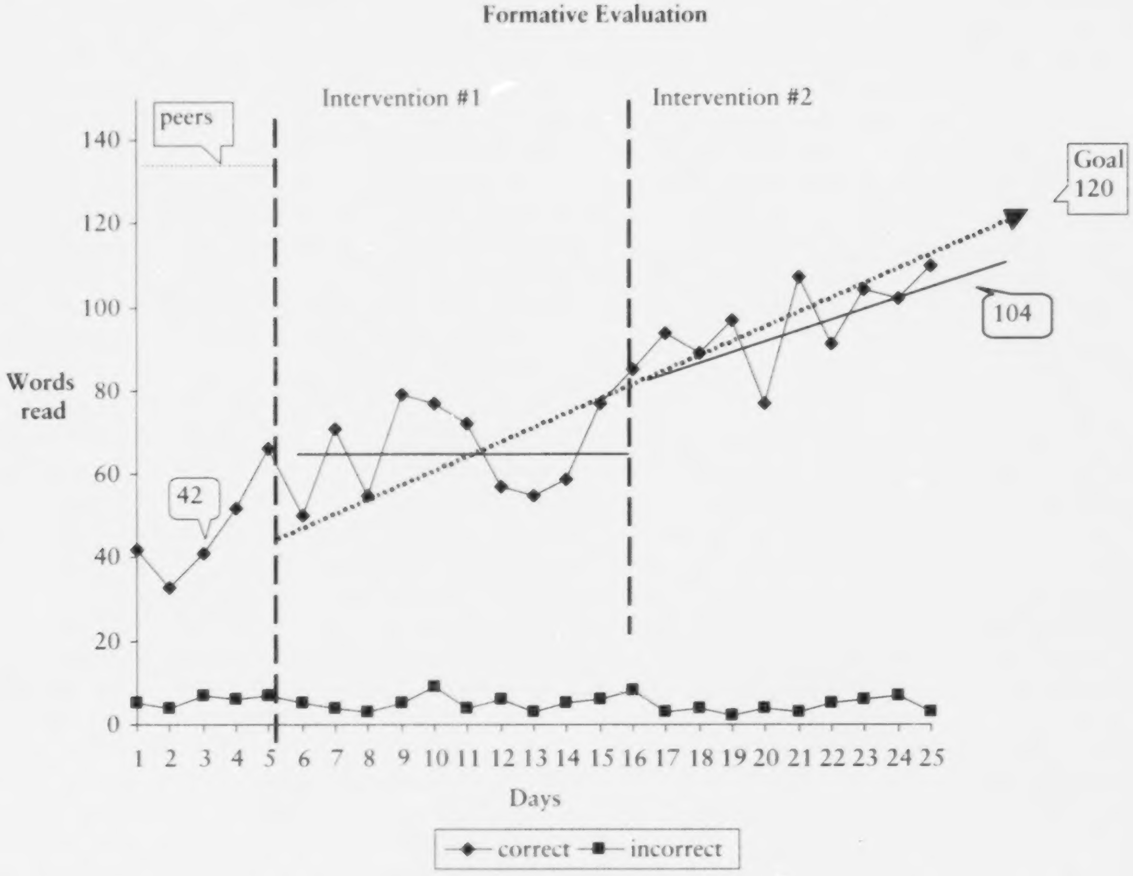
PROGRESS MONITORING

In general, procedures for individual progress monitoring are based on direct and frequent observation of performance on the tasks or in the situations that represent the essential outcome of the intervention. Repeated measurement of performance occurs before, during, and at the end of interventions producing a series of data points across time. The time series data enable us to make the usual estimate of current performance level available through single occasion testing, but it also enables us to estimate trends in performance before and after intervention, and changes in individual variability. Estimates of trend and variability prior to program reform are derived from repeated measurements to establish a baseline for these characteristics. Trend and variability in individual baseline performance are then combined with initial level to create a stronger database for testing intervention effects. Evidence exists that when individual progress monitoring is used in a formative evaluation design, intervention effectiveness can be increased (Fuchs and Fuchs, 1986). The most probable explanation for this increased intervention success is that the empirical records of intervention effects are continuously available for use in deciding whether a program is producing intended effects and should be continued, or is ineffective and should be modified or abandoned.

An illustration of how individual progress monitoring can serve as an aid to testing successive intervention attempts is presented in Figure 1. As can be seen in the figure, the progress monitoring data reveal that initial effort to improve the student's reading performance was relatively unsuccessful and that an alternative approach to teaching the student to read was needed. After a series of trials, a collaborative program involving direct instruction was created and the trend in the student's reading performance shifted upward.

Such a graphic record is important because it clarifies many things for decision makers. First, it clearly represents the difference between the student's initial level of performance and the standard of performance desired by the teacher. Second, by projecting the trend from the student's baseline performance to the goal date at the end of the graph, it is possible to estimate the magnitude of the difference that would be obtained on the goal date if no program reform occurred. Third, when the rate of growth in performance required to attain the desired level on the goal date is drawn on the graph, it provides continuous feedback on progress toward the goal. Finally, the degree of program improvement produced by each successive reform can be estimated by contrasting the performance trends produced during successive reforms. This more dynamic picture of performance

Figure 1. Progress monitoring graph for reading



in relation to changes in student programs, then, creates a richer database for formatively evaluating program reforms than is available through pre- and post-testing of individual student performance.

PROGRESS INDICATORS

As with any effort to base decisions on measures of performance, successful use of individual progress monitoring necessitates that the data used for decision making validly represent the goals of program intervention. Unfortunately, despite widespread interest in assessing educational outcomes, very little agreement exists regarding the data that are reliable and valid indicators of the culturally valued outcomes of schooling. In the absence of a research basis for indicator selection, "authenticity" (Wiggins, 1993) and "social validity" (Wolf, 1978) are currently the most highly touted characteristics of data on program outcomes. While these characteristics are not well defined, the essence of authenticity seems to be that individual performance on tasks that are "real" and "meaningful" be observed as a basis for appraising competence. While this concept is laudable in the abstract, efforts to operationalize authenticity encounter both technical and logistical problems. Nevertheless, good reasons exist to consider the authenticity of the tasks on which we appraise performance. Perhaps authenticity can be partly assured through establishing social validity; that is, the degree to which significant others in the individual's environment agree that the data to be collected represent the important treatment goals.

When authenticity and social validity are used as criteria for evaluating the use of standardized achievement tests it is easy see why they have been subject to so much criticism. A standardized reading achievement test, for example, might include a variety of paper and pencil tasks such as recognizing isolated words, selecting definitions of words, and selecting multiple choice responses relative to the content of short segments of text. While ample psychometric evidence may exist for the reliability and validity of the data produced through measures of student performance, such tests are criticized on the grounds that the tasks are not authentic; that is, that they are not what people do when reading. An argument can be developed that a more authentic reading task involves sharing or communicating reactions or feelings in regards to the content of a story. If so, then assessment should be structured around the social and communicative aspects of the reading experience rather than around arbitrarily selected words and questions from a text that was not selected by students out of their own interests.

In contrast to authenticity, determining the social validity of such a standardized test is based on the values of those invested in student performance. If they are less interested in scores on such a test than whether the students are using their reading skills to successfully complete relevant school assignments, then the socially valid information would be student performance on school assignments rather than their scores on the standardized test. We should remember, however, that social validity is based on shared values rather than independent judgments of authenticity. For that reason it is possible for performance on such a standardized test to be judged as socially valid but not authentic.

Another important set of characteristics with respect to useful progress indicators relates to practical and logistical concerns. If frequent measurement of progress is useful for ascertaining intervention effects, then assessment procedures must be efficient and economical. That is one reason why the administration of commercially developed achievement tests cannot be used in frequent progress monitoring. Frequent monitoring also necessitates that multiple equivalent forms be used so that practice effects on the test itself do not accrue. Thus far, direct observation and recording of relatively brief performance samples embedded within the context of ongoing classroom activities has proved to be the most practical and logistically feasible solution to these problems (Deno, 1997).

APPROACHES TO DECISION MAKING

Evidence has accumulated that program reforms are more successful when systematic data decision rules have been used to make program improvement decisions (Fuchs & Fuchs, 1986; Fuchs, Fuchs, & Deno, 1985). The research in this area reveals that people will collect data on the existence of a problem and then monitor progress toward goals, but tend not to use the data to make timely changes in unsuccessful interventions. Indeed, this failure to modify programs in response to performance data has been identified by program administrators as the primary barrier to effective system level implementation of CBM procedures in special education programs (Yell, Deno, & Marston, 1992). At least two approaches to overcoming this barrier are available and may be effective.

The first solution to getting interventionists to use progress-monitoring data is to use computer technology to prompt responsiveness to the data. In this approach a structure is created for determining when and how a program might be modified to increase the likelihood of its success. Evidence indicates that the use of such a technology does, indeed, result in more effective programs (Fuchs, Fuchs, Hamlett, & Ferguson 1992). The second solution is to devote greater resources to developing and supporting professional practices consistent with effective use of progress monitoring data to solve problems. This will require preservice and inservice training and accountability systems that encourage effective use of progress monitoring to formatively evaluate efforts to solve problems. As a relatively new practice, a data-based approach to problem solving must evolve as part of the natural practice of school psychology. As with any evolutionary outcome, the behaviors that become the "best practices" of school psychology will be determined by the degree to which those practices are adaptive for school psychologists. If survival in the culture of the schools requires the effective use of data-based problem solving, we can predict that school psychologists will successfully adapt to that culture and will learn to use effective data-based problem-solving procedures. System developers and managers must look to themselves if they want to identify the source of motivation for best practice.

SUMMARY

The foregoing discussion has focused on the role of the school psychologist in solving special educational problems. Specialized training in assessment enables school psychologists to play a key role in creating the database for effective problem solving. To do so, however, requires that they have a clear conception of the problem-solving model and their role in that process. A problem-solving approach to assessment moves school psychologists from the role of special education gatekeeper to a role rich with possibilities for ongoing collaborative intervention with classroom teachers.

Best Practices in School Psychology and the Law

David P. Prasse
Loyola University, Chicago

INTRODUCTION

School psychology has been and continues to be influenced by various legal sources including legislation and judicial decision. Our profession has experienced an increase in that influence along with the inevitable accompanying professional and public scrutiny of the disciplines' practices and policies. While many components of psychology and education are subject to legally defined parameters, school psychology, due in part to historical ties to special education, has realized a significant legal impact that has modified roles, responsibilities, and the delivery of school psychological services in general. Indeed, of the four applied professional areas of psychology, school psychology is most likely influenced more than the other three (clinical, counseling, and industrial/organizational) because school psychologists are primarily employed by public schools. Reschly and Bersoff (1999) state it this way: "To a very great extent, state and federal laws create the requirements that lead to employment for school psychologists and, with this benefit, comes significant legal regulation over how school psychology will be practiced"(p. 1077).

As the programs and practices of education have undergone radical change as a result of judicial and legislative influence, so too have the service delivery components of school psychology. Courts, in their role as mediator between the rights of students and parents and the rights/responsibilities of schools, have moved to protect and define procedural and substantive due process for students, especially students with disabilities. Courts have instructed school systems to provide special education programs where there has been an absence of programs or where inadequate programs have not met the educational needs of students. The legislative influence of P.L. 94-142, The Education of all Handicapped Children Act (EHA) (1975) along with subsequent revisions, Section 504 of the Rehabilitation Act (1973), the Americans with Disabilities Act (1990), and more recently substantive revisions to the Individuals with Disabilities Education Act (IDEA, 1997), are well known and much of the legal influence on the discipline of school psychology is a result of these and similar state-based legislation. Understanding the scope of legal influence on school psychology is fundamental to a comprehensive knowledge of best practices.

As the legal parameters change, so does the school psychology/law relationship. This constant state of flux means that which is mandated or required today may change tomorrow. A practice or process followed yesterday (or today) may be judged inappropriate or illegal in the future! As societal priorities change and individual rights are further defined, legal requirements change and the parameters of influence expand and/or constrict. Where there exist "fundamentals" of law that, for the most part, remain stable across time, the daily practices and service delivery approaches are susceptible to legislative and judicial interpretation of those fundamental legal principles.

What follows is a review of legal principles that serve as a foundation for best practice. Best practice within the context of legal influence is understood to mean not only compliance with legal mandates but also delivery of school psychological services consistent with services established in the *School psychology: A blueprint for training and practice* (National Association of School Psychologists, 1997). The purpose of this chapter is to review what we know about the influence of law on school psychology in the schools and therefore what we expect all school psychologists to know and understand. The intent is not to provide detail about the specifics of best practice but rather to highlight the areas of knowledge regarding school psychology and the law that should be known to all who practice school psychology.

BASIC CONSIDERATIONS

Sources of Legal Influence

There exists a sequential nature to sources of law that reflect (in most cases) application of broad principles to specific situations. It is expected that specific laws, practices, and procedures are consistent with broad principles. Understanding the broad principles provides the foundation upon which we problem solve specific situations. The sources of law are, for the most part, hierarchical as follows:

Federal Constitution
↓
Federal Statute
↓
State Constitution
↓
State Statute
↓
Administrative Rules
↓
Local Policy and Procedure

Sources of law are more influential (i.e. having greater impact) the higher they are in the hierarchy. Sources of law are sequentially subordinate and those that exist beneath others are narrower in scope and applicability. However, on occasion these same lower order sources may be no less important than those sources higher in the hierarchy.

CONSTITUTION

The cornerstone of all law is the U.S. Constitution. Sources of law (federal and state statutes, judicial decisions, etc.) are subject to the provisions of the Constitution. Laws, practices, and procedures not congruent with principles established by the Constitution are eventually judged (usually by a court) as unacceptable.

The U.S. Constitution has nothing directly to say about education, yet everything to say about the manner in which education (including school psychological services) is provided to the public. There is no Constitutional right or guarantee to an education. Providing an education to the public is a matter left to the individual states by way of the Tenth Amendment, which states:

> The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively.

Therefore, states may provide a public education to its citizens. In so doing, the state must do so in a manner that is compatible with the principles established by the Constitution.

It is this requirement that impacts the delivery of school psychological services. As an aspect of public education, school psychological services must adhere (as education in general) to established constitutional principles. When the practices and procedures of school psychology violate those principles, they will likely be viewed as unacceptable. Knowledge of these fundamental constitutional principles and the legislation and litigation that builds on them is necessary to effective problem solving when weighing the legal parameters associated with delivering school psychological services.

LEGISLATION

Legislation, or statute, is the most influential source of law affecting the delivery of educational and school psychological services. Enacted by Congress or state legislatures, legislation is created to provide the mechanism for implementing constitutional guarantees or for the purpose of initiating specific programs. Federal legislation important to school psychology is either program legislation or civil rights legislation. Program legislation provides funds for delivering specific programs (e.g. Chapter I, Special Education), and in providing these funds mandates that agencies (e.g. schools) delivering the services do so in a manner prescribed by the legislation. The *Individuals with Disabilities Education Act Amendments of 1997* is among the most widely known. Its precursor was the *Individuals with Disabilities Education Act of 1990* and the *Education for All Handicapped Children Act of 1975*, most often referred to as P.L. 94-142. Through IDEA, funds (albeit limited) are made available for educating children with disabilities. The procedures by which these educational services are delivered are specified by the legislation and recipients are obligated to comply with the requirements. Civil rights legislation differs in that requirements are usually not tied to program funding; that is, procedures mandated by the law must be adhered to even in the absence of funds tied directly to a program. *Section 504 of the Rehabilitation Act of 1973* and the *Americans with Disabilities Act of 1990* are relevant examples of this type of legislation.

State statutes serve to enact the principles established by a state constitution or federal mandate and may be quite specific and detailed. For example, most states have a compulsory school attendance law and a law that provides for educating children with disabilities. The later must be compatible with Constitutional principles and requirements delineated in IDEA and Section 504. State laws affecting education are wide ranging and differ from state to state. For example, mandatory child abuse reporting laws may or may not detail the precise steps necessary for reporting suspected abuse. Direct and indirect impact on school psychology will vary accordingly.

ADMINISTRATIVE RULES

When a law is enacted, a specific governmental agency is charged with implementing the requirements of the statute. Inasmuch as the legislation may not include all the specific details necessary for successful implementation, the appropriate governmental agency is empowered to write rules to accompany the newly enacted law. When adopted, these rules are equivalent in importance and influence to the statute itself. At the federal level a statute pertaining to education is usually administered by the Department of Education, which is then responsible for developing corresponding rules. At the state level, the relevant agency is frequently the Department of Public Instruction or Education and has similar responsibilities to those found at the federal level. These governmental agencies will usually "propose" rules, hold public hearings, and finally adopt the rules. Paying close attention to the rule-making process as well as possessing a thorough knowledge of the final rules is a necessary and crucial component for understanding the intent and specific requirements of a particular law.

Litigation/Case Law

Litigation is the source of and knowledge base for law that we refer to as case law. The influence of judicial decision making is predicated, in part, on the judicial structure itself. There exists a federal court system and individual state court system. The federal system includes three levels: U.S. District Courts (trial courts where trials are conducted); U.S. Court of Appeals (13 judicial circuits); and the U.S. Supreme Court (court of last resort). Generally, the federal judicial system is used when the question involves a Constitutional issue or a federal statute. Each state has its own judicial system, and each system varies greatly. Like the federal system there are different levels often including circuit or trial courts, one or two levels of appellate courts, and a state "supreme" court.

The import of a judicial decision depends, in part, on the level of court in which the issue is adjudicated. Generally, the higher a court is in the system, the greater the impact or influence. For example, a state supreme court decision is applicable to that particular state, while a decision rendered by a U.S. Court of Appeals is applicable to that entire district which, except for the District of Columbia and one dealing with special patents and copyright issues, includes several states. Decisions of the Supreme Court are applicable to all states and effectively become the law of the land. The higher the court in the judicial hierarchy the more authoritative its decision and accompanying opinion.

The fundamental purpose of judicial decision is to resolve conflict—conflict that arises from two different interpretations of a statute or from questions embodied in a state or the federal Constitution. Judicial decisions involve determining the intent of the legislature and the compatibility of that intent and/or practices with constitutional principles. Statutes or practices that violate constitutional principles are then overturned or modified by the court. The potential impact or influence of case law is thus twofold. First, the jurisdiction of the court (where it is in the hierarchy) determines the influence of the decision. Second is the cumulative influence established through a series of decisions that when taken together establish a clear and unequivocal trend, pattern or precedent.

PROFESSIONAL STANDARDS AND ETHICAL CODES

Professional standards or ethical codes represent an additional (albeit indirect) source of legal influence on the discipline of school psychology. (See Jacob, this volume, for coverage of ethical practice). Standards that directly bear on school psychology include the *Principles for Professional Ethics* (National Association of School Psychologists, 2000a), *Ethical Principles of Psychologists and Code of Conduct* (American Psychological Association, 1992), *Standards for Training and Field Placement Programs in School Psychology* (National Association of School Psychologists, 2000b), and *Standards for Educational and Psychological Tests* (American Psychological Association, American Education Research Association, & National Council on Measurement in Education, 1984). In addition, most state school psychology associations have adopted professional practice codes.

Although important to the overall process of shaping and monitoring behavior of school psychologists, professional standards are not, at least in the traditional sense, "the law" and therefore do not carry the same weight or influence as statutes or case law. Professional standards interface with the law, and as such, are not free to develop from discipline preferences alone. The existence of a standard in the National Association of School Psychologists *Principles* that states, "School psychologists avoid any action that could violate or diminish civil and legal rights of clients" is clear acknowledgement of this interface.

Nonetheless, professional standards are very important to the profession (including the consumers of services) in that they represent consensual thinking with respect to best practices. They become the standard by which professional behavior is judged by both peers and on occasion the courts. Courts have and continue to refer to professional standards when reviewing the behavior of an individual psychologist and when reviewing the procedures and policies of service delivery systems. In the legal arena, the "clout" of professional standards may be described as a dynamic state of potential. That is, if a court considers professional standards during deliberations and bases decisions (even in part) on professional standards, then those standards become (at least in that particular case) like the law. The more times that occurs, the stronger is the "legal" influence of professional standards.

BEST PRACTICE: LEGAL FOUNDATIONS FOR PROBLEM SOLVING DELIVERY SYSTEMS

Attempts to define or describe best practice with respect to school psychology and the law is challenging for two reasons. First, as stated earlier, law or legal influence is dynamic. Requirements, restrictions, and parameters around professional practice tend to change, sometimes with short notice. Second, legal influence on practice is subject to interpretation. Professional opinions (both psychologists and lawyers) differ with regard to not only basic legal principles but also as to how specific requirements should be implemented. The "correct way" to deliver services is then open to debate.

What should be known by school psychologists about the law is tied to a few fundamental and important areas. They are fundamental, for they serve as the basis for day-by-day problem solving. They include an understanding of specific components of the Constitution, certain procedures and principles that flow from the Constitution, an understanding of children's rights, and, finally, specifics of relevant legislation and litigation. We turn first to the Constitution.

THE CONSTITUTIONAL FOUNDATION

A theme that permeates discussion with respect to legal requirements and mandates for school psychology is *May we do this?* or *Will I be held liable for this?* Delivering school psychological services in a problem solving delivery system is, in large part, dependent on understanding the *intent* of the law (case or statute) that emanates from fundamental constitutional principles. To understand these principles is to know the foundation for judicial decision, which provides a knowledge base from which specific practice questions are answered.

The Constitutional principles relevant to judicial decisions and legislation are relatively few in number. As indicated earlier, it is the Tenth Amendment that establishes education as a state function. Other relevant Amendments include the First and Fourteenth. The Fourteenth Amendment has been most influential with respect to special education and school psychological services, for many court decisions that have clarified the rights of children and educational practice have, in large part, been based on this Amendment. The Fourteenth Amendment states, in part:

> No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty, or property without due process of law, nor deny to any person within its jurisdiction the equal protection of the laws.

Application of the Fourteenth Amendment to education and school psychology is understood through a brief elaboration of the two clauses: the due process clause and the equal protection clause. Application of the Fourteenth Amendment by courts to services provided in the schools means that most actions respecting children with disabilities (or suspected disabilities) must guarantee equal protection and due process.

EQUAL PROTECTION AND THE RIGHT TO AN EDUCATION

Equal protection guarantees a person the same rights and benefits all other citizens enjoy with respect to their government (e.g., schools) unless the withholding of those rights and benefits is for a valid reason that justifies the state in singling out the person for differential treatment. As stated earlier, there is no federal constitutional right to an education. However, when states choose to provide an education to its citizens (as all states do) they must do so in a manner that is acceptable to fundamental constitutional provisions. Judicial intrusion into the educational arena has been mixed. However, the judicial cornerstone applying the equal protection clause to education and providing an equal educational opportunity for all children, including those with disabilities, is *Brown v. Board of Education* (1954). Reversing almost 60 years of judicially supported segregation (*Plessy v. Ferguson*, 1896), *Brown* addressed the applicability of the equal protection clause to public education. The *Brown* decision established that educating minority children in separate but "equal" facilities violated the equal protection clause of the Fourteenth Amendment and therefore denied them an equal educational opportunity. The reasoning of the Court was that education became a property interest when states made it available to its citizens and the notion of separate but equal was inherently unequal.

When the Court found this practice violated the equal protection clause, it established the foundation upon which the exclusion of children with disabilities from school would subsequently be challenged. That challenge was helped by the Court's decision in *Brown* that made clear the applicability of the Fourteenth Amendment to the public school arena. Indeed, the rationale and precedent established by the Court should be critically considered as potentially applicable to the current debate surrounding inclusion. It was against the backdrop of *Brown* and the political promise of equality and equal opportunity emerging in the 1950's and 1960's that the hope for educating children with disabilities emerged.

DUE PROCESS

Due process as a requirement of law and as a component of delivering educational services is derived primarily from the Fourteenth Amendment. Turnbull and Turnball (2000) refer to procedural due process as the legal expression of fairness. There are certain rights and privileges that a state may not arbitrarily take from a citizen (in this case student or parent) and that the state (school district) may not act unreasonably, arbitrarily, or capriciously in dealing with a citizen (student). Procedural due process "is a flexible concept whose precise contours change relative to the nature and gravity of the interest infringed" (Bersoff & Prasse, 1978, p. 402). So the due process clause of the Fourteenth Amendment requires that no person may be deprived of life, liberty, or property without due process of law. As stated by Reschly and Bersoff (1999), "Due process is a mechanism that is intended to ensure fundamental fairness in decision making" (p. 1078).

We have made clear that education is not a right guaranteed by the Constitution, but is instead, a duty left to the states via the Tenth Amendment. Yet, the due process and equal protection components of the Fourteenth Amendment are made applicable to the delivery of educational and psychological services as a function of case law. The reason for that is that education is considered a property right and may not, therefore, be taken away arbitrarily and without due process of law (*Goss v. Lopez*, 1975).

Judicial application and interpretation of the Fourteenth Amendment is a continuous and dynamic process. Court decisions range from establishing an equal educational opportunity for persons with disabilities to mandating assessment practices that do not result in disproportionate placement or overrepresentation of minorities. Among the procedures affecting school psychological services that are required by dint of the Fourteenth Amendment are:

1. Written notice to parents if a school proposes to change or refuses to change, the identification, evaluation, or educational placement of the child.
2. Providing parents an opportunity to present complaints with respect to any matter relating to the identification, evaluation, or educational placement of their child.
3. Procedural requirements of informed written consent prior to assessment and special class programming.
4. All requirements specific to nondiscriminatory assessment.

Application of the Fourteenth Amendment to the educational arena for children with disabilities resulted in dramatic change. It opened the school house door to children with disabilities.

PROGRAM AVAILABILITY

Legal influence on educational programming is an outgrowth of litigation involving the provision of educational services to children with disabilities. It was litigation and later legislation that resulted in various mandates to provide an education to children, particularly the child with disabilities. The legal foundation for requiring equal educational opportunity for children with disabilities is the equal protection clause. By applying the equal protection clause of the Fourteenth Amendment to education, courts created the fundamental concept of an equal educational opportunity thereby precluding states from excluding from its schools children with disabilities. For many years children with disabilities were excluded from public schools and were often out of school altogether or shunted to inappropriate institutions.

The precedent-setting cases that challenged school systems and states that systematically denied a free public education to the disabled include *PARC (Pennsylvania Association for Retarded Citizens [PARC]) v. Commonwealth of Pennsylvania* (1972) and *Mills v. Board of Education of the District of Columbia* (1972). *PARC* challenged the exclusion of mentally retarded children from school who were deemed "uneducable" or unable to profit from an education on the basis that such exclusion violated their equal protection and due process rights. The consent decree set forth important principles including the notion of individualized education, no extra costs for parents simply because their child was disabled, and various due process requirements. The case, receiving national media attention, served as an impetus for similar litigation throughout the country.

The children represented in *Mills* were denied an equal educational opportunity as a result of their various handicapping conditions and the district denied them an education by utilizing procedures of suspension, exclusion, and class reassignment. In addition, their due process rights were denied when the district assigned them to special classes, precluding them from access to regular education programs. In finding for the plaintiffs the court dismissed limited financial resources as a basis for the denial of equal educational opportunity and ordered an equal expenditure of funds so that no child would be excluded from a publicly supported education. *Mills*, unlike *PARC*, applied not only to mentally retarded children but to other handicapped conditions as well. Together these cases served as a basis for the development of federal legislation, particularly, P.L. 94-142, requiring equal educational opportunity for children with disabilities. Indeed it was the due process provisions of *Mills* that served as the foundation for the specific requirements that were to emerge in the Education for All Handicapped Children Act of 1975 (EAHCA).

THE LEGISLATIVE FOUNDATION

Although pervasive in their impact on school psychological services, the federal laws that shape daily practice are actually few in number. However, they are comprehensive and detailed in coverage, and more then any other source have influenced the practices and procedures of school psychology. Earlier program or funding legislation was distinguished from civil rights or anti-discrimination legislation. The statutory provisions of Section 504 of the Rehabilitation Act are requirements that attempt to ensure disabled persons are not discriminated against.

Section 504 of the Rehabilitation Act. Adopted in 1973 as an amendment to an older law that focused on vocational rehabilitation regarding employment, the 1973 Rehabilitation Act provided that recipients of federal financial assistance could not discriminate on the basis of a handicap. Although adopted in 1973, the implementing regulations were not approved until 1977. Section 504 (as it is often referred to) is civil rights legislation, and is similar therefore to other anti-discrimination legislation such as that dealing with race (Title VI) and gender (Title IX). Ensuring compliance is then the responsibility of the Office of Civil Rights, not the U.S. Department of Education. The over arching requirement is that *all* recipients of federal funds not discriminate against an otherwise qualified disabled individual on the basis of disability. As such, requirements extend to many institutions (public and private) including business, health care, and of course schools.

Section 504 defines a disabled person as follows:

> any person who (i) has a physical or mental impairment which substantially limits one or more of such person's major life activities, (ii) has a record of such an impairment, or (iii) is regarded as having such an impairment. [29 U.S.C. Sec.706 (7)(B)].

Physical or mental impairment includes physiological disorders or conditions, including cosmetic disfigurement, and mental or psychological disorder includes mental retardation, organic brain syndrome, emotional or mental illness and specific learning disabilities. Major life activities are "functions such as caring for one's self, performing manual tasks, walking, seeing, hearing, speaking, breathing, learning and working."(34 C.F.R. Part. 104.3).

Section 504 (Subpart D) requires that districts provide a "free appropriate public education" (FAPE) to each qualified person with a disability, regardless of the nature or severity of the disability. Districts are required to provide a full range of special accommodations and services necessary for students with disabilities to participate in and benefit from public education programs and activities.

Under Section 504 a free appropriate public education requires districts to follow procedures that ensure:

1. Nondiscriminatory evaluation and placement procedures.
2. Periodic re-evaluation of handicapped students.
3. Educational services that meet individual educational needs.
4. Educational services equal in quality to that provided for non-disabled students.
5. To the maximum intent possible, educating disabled students with non-disabled students.
6. Due process procedures that ensure parent participation in evaluation and placement decisions and provides for an impartial hearing with parent representation by counsel.

A determination under Section 504 that a student has a disability does not necessarily mean that the student would be declared disabled according to the criteria specified under IDEA. In those cases students' educational needs must be provided for by general education programs, and specific individualized educational needs met through the resources of general education.

Americans with Disabilities Act. Unlike Section 504, which covers only recipients of federal financial assistance, the Americans with Disabilities Act (ADA, 1990) is a civil rights law that prohibits the discrimination of people with disabilities in programs and activities, public and private, and ensures, therefore, the civil rights of all those with disabilities. The ADA represents the most comprehensive piece of civil rights legislation directed toward the disabled or those who are regarded as disabled that Congress has ever enacted. The applicability of the ADA does not distinguish between public and private institutions, and extends its requirements to education, employment, and state and local government.

The fundamental premise of the ADA is to extend equal protection/opportunity to those who are (or are regarded as) disabled. The definition of disabled set forth in the ADA is similar to that found in Section 504. It is applicable to an individual who has, has a history of having, or is regarded as having an impairment that significantly limits one or more of life's major functions.

The specific section of the ADA applicable to education is Title II, Subtitle A. This section applies directly to public schools and is quite similar in language to that of Section 504. It not only prohibits discrimination on the basis of a disability, but also requires schools to make reasonable accommodations for students with disabilities. The requirements include, among others, notice regarding these provisions, due process procedures, and providing education in integrated settings (inclusion). In general, the ADA requires full compliance with Section 504 and sometimes more than is required by Section 504 (Jacob-Timm & Hartshorne, 1994).

The applicability of the ADA to identified students with disabilities is mitigated, in part, by litigation brought under the ADA in employment discrimination. The ADA prohibits discrimination against those who are disabled but "otherwise qualified" to perform the basic duties of the job, with or without reasonable accommodation. Recently, the Supreme Court reached similar conclusions in three cases that bear directly on the applicability of the ADA (*Albertsons, Inc. v. Kirkingburg*,1999; *Sutton v. United Air Lines, Inc.*, 1999; *Murphy v. United Parcel Service, Inc.*, 1999). In each case, the Court reached a conclusion that determining whether a person has a disability and is protected by ADA is mitigated by measures that might "correct" the disability. If those measures reduce the impairment resulting in no significant limitations (as defined in the ADA) then the individual is not "disabled" under ADA (Turnbull & Turnbull, 2000). There are several implications for those students who are disabled. If their disability is "corrected" via an intervention (e.g., medication) they are no longer eligible to bring a claim under the ADA. The Court's interpretation of the ADA may eventually impact litigation brought under Section 504, as the language in each is so similar (Turnbull & Turnbull, 2000).

Individuals with Disabilities Education Act. Triggered, in part, by the litigation of *PARC* and *Mills*, Congress, in 1974, passed a funding bill that required states to adopt goals that would ensure equal educational opportunities to all handicapped children. Establishing such goals was a condition for receiving federal funds (P.L.93-380). The following year Congress passed EAHCA, which became effective in 1977. In 1990, Congress amended the EAHCA and retitled the law as the Individuals with Disabilities Education Act (P.L.101-476, 20 U.S.C. Sec. 1400 [a]). Finally, in 1997 Congress amended the IDEA again, through reauthorization. The IDEA Amendments of 1997 (P.L. 105-17) is the most significant special education legislation adopted in the past 22 years. While the fundamental requirements of providing FAPE remain in place, IDEA 1997 clarifies that special education is no longer a *place* but a *set of services* (Prasse & Schrag, 1999).

The adoption of legislation mandating an equal educational opportunity to students with disabilities brought with it cornerstones of service delivery that continue to shape the practice and procedures for delivering both special education and school psychology services. These cornerstones remain the foundation for problem solving many of the questions that arise about delivering services to students with disabilities. These broad principles help us understand what is operationally meant by FAPE.

Zero Reject. IDEA (as well as Section 504) makes it clear that all children are to be afforded an equal educational opportunity and states may not deny an education on the basis of a disability. Further, the law requires that states be affirmative in seeking out those who are disabled through "child find" activities. Extending an education to all disabled students today means those eligible students ages birth through 21. In addition, the severity of the disability is not a reason to deny an otherwise eligible student an education. As a result, we have come to accept an expanded definition of education to include even basic and fundamental life skills such as feeding and toilet training. Students may not be excluded from school only on the basis of a disability, and if a student's behavior at school is disruptive yet caused by the disability, schools remain obligated to provide for the student's education (Buesing & Prasse, 1991). Changes to IDEA 1997 attempted to clarify the relationship between disability, behavior, and school disciplinary action. If the student's behavior is a manifestation of the disability, then the school may discipline, but is restricted both by procedures and type of discipline. If the behavior is a manifestation of the disability, then the school must reevaluate the current educational program. While students may be suspended for 10 days, they are protected by the "stay put" provision if the change in program proposed by the school is contested by the parent. Schools that move to suspend for more than 10 days are affected by the "stay put" provision and must conduct a functional assessment of behavior (FAB) and develop a behavioral intervention plan. Students who pose a danger to themselves or others may be removed from school and provided an alternative education program.

Appropriate Education. Since the adoption of the federal law requiring public schools to provide an equal education opportunity to students with disabilities, the notion of what is an appropriate education has proven to be one of the most dynamic and evolving principles of the law. Professionals have debated issues of appropriate education in the literature while courts have rendered increasingly specific decisions that further define what is meant by appropriate.

To help determine what is appropriate, courts have turned to two key components required of districts when implementing FAPE. They are the *Individualized Education Program* (IEP) and *Least Restrictive Environment*. As a requirement of IDEA, the legal definition of an IEP means a statement of the child's present levels of educational performance, including

1. How the child's disability affects the child's involvement and progress in the general curriculum (i.e., the same curriculum as for nondisabled children).

2. A statement of measurable annual goals, including benchmarks or short-term objects (that relate to how the child will be involved in and progress in the general curriculum).

3. A statement of the special education and related services and supplementary aids and services and a statement of program modification or supports that will be provided the child.

4. An explanation of the extent, if any, the child will not participate with nondisabled children in regular class.

5. A statement of any individual modifications in the administration of statewide or district-wide assessments of student achievement (IDEA 1997 requires students with disabilities to participate in these assessments unless the district determines participation for that student to be inappropriate).

6. A statement of how the child's progress toward annual goals will be measured and how the child's parents will be informed of that progress(34 C.F.R. Sec. 300.347).

Least restrictive environment requires "that to the maximum extent appropriate, handicapped children, including children in public or private institutions or other care facilities are educated with children who are not handicapped"(34 C.F.R. Sec. 300.550[b][1]). The legal definition continues with a requirement that "special classes, separate schooling or other removal of handicapped children from the regular educational environment occurs only if the nature or severity of the handicap is such that education in regular classes with the use of supplementary aids and services cannot be achieved satisfactorily" (34 C.F.R. Sec. 300.551[b][2]).

Individualized Education Program. The requirement that a school district develop a plan (as outlined above) unique (individualized) to a student's educational needs that includes goals, objectives, and time lines for implementation has been used by the Supreme Court as one basis by which to judge the Congressional intent of the meaning of an appropriate education. In *Board of Education of the Hendrick Hudson Central School v. Rowley* (1982) the Supreme Court dealt for the first time with the question of what constitutes an appropriate education. Deciding whether or not a deaf child required an interpreter (as a related service), the Court ruled that the interpreter was not required under the law. In reaching this decision the Court emphasized the legislative history of P.L. 94-142 and concluded that the intention of Congress was not to maximize development of students with disabilities. Rather it was to grant access to educational opportunity and provide a reasonable opportunity to learn. Noting that the student had learned and progressed from grade to grade and that the professionals who developed the IEP acted according to correct "procedures," the Court concluded the district had satisfied the intent of what is referred to as the "open door" policy or, in other words, provided comparable treatment. Therefore, in the opinion of the Court the intent of IDEA is to provide a reasonable opportunity for students to learn, not necessarily to maximize their potential.

The relevance of *Rowley* to the IEP and an appropriate education is noted when the Court affirmed what might be termed a process definition of the IEP. That is, if the IEP was developed procedurally in a manner compatible with the requirements of IDEA, then it will be deemed appropriate. An IEP developed by a group of professionals and parents becomes, then, the basis or cornerstone for individualizing an education program. The *Rowley* decision affirmed that what was meant, in part, by appropriate education is gleaned from an overall understanding of IDEA which emphasizes process and inputs rather than results and outputs (Turnbull & Turnball, 2000), an emphasis that would change with IDEA 97.

The relevance of the IEP to judging an appropriate education was strengthened in *Irving Independent School District v. Tatro* (1984). The fundamental question involved was whether or not Clean Intermittent Catheterization (CIC) was a necessary related service or was it excluded as a medical service as is provided under IDEA. The child in question had spina bifida with orthopedic impairments, and she required CIC assistance during the school day. The requirement was not mentioned as a component of the IEP and, as such, the district refused to administer it.

The Court affirmed the Tatro's claim that their child was entitled to CIC. The Court ruled that CIC is a related service as defined under IDEA, for it is a service that provides a meaningful access to an education. Necessary to the decision was to rule CIC a school health service and not a medical service.

With regard to an appropriate education the implication of the *Tatro* decision is two fold. First the decision affirms judicial review regarding the appropriateness of the IEP. Going therefore a step beyond *Rowley* the Court made clear their intent to judge the appropriate education standard not only on the basis of adherence to procedural safeguards, but on the basis of substance and content as well. The Court did review the content and substance of the IEP and found it wanting. On the heals of *Tatro*, the Supreme Court considered the question of what constitutes an appropriate education and IEP in *Cedar Rapids Community School District v. Garret F.* (1999). At age four, Garret was paralyzed in a motorcycle accident. He spoke and controlled his wheelchair via breath through a straw. He required a ventilator to breathe and someone to attend to physical needs while in school. By fifth grade his mother requested the district to pay for the health care services and the district refused. The central question before the Court was whether the definition of "related services" required the school district to provide Garret with certain nursing services during school hours. Affirming the decision of the Court of Appeals, the Supreme Court held the school district responsible for providing and funding the related services for Garret while in school. In so doing, the Court made clear that these services were not medical services as defined in the law, but rather school health services and thereby affirmed Garret's right to attend school with his peers. Each of these decisions serve to broaden the construct of related services to not only enable the child to benefit but to obtain access to educational services.

Least Restrictive Environment and Inclusion. The judicial cornerstone for educating children with disabilities with children who are not disabled is over 40 years old, for it was *Brown v. Board of Education* (1954) that applied the equal protection clause of the Fourteenth Amendment to the issue of racial segregation in our public schools. Holding that separation is inherently unequal, the Supreme Court set forth the argument that education, when guaranteed by a state, is a property interest and must therefore be delivered in a manner that affords due process of law and equal protection of the laws. The principles set forth in *Brown* became the basis for subsequent litigation that forced the public schools to extend an equal educational opportunity to children with disabilities (*PARC v. Pennsylvania*, 1972; *Mills v. Board of Education*, 1972). Separating children (either on the basis of race or disability) became, then, a practice that was considered unacceptable if not illegal, and at both the state and federal level legislation emerged that not only required an equal educational opportunity for the disabled student but also required that it be delivered in a "least restrictive environment." The requirement is nested in the judicial holding that separate is not equal, and separation stigmatizes. In addition, interacting with non-disabled peers is considered an essential activity in the education and development of disabled students.

IDEA 1997 defines least restrictive environment (LRE) as follows:

> To the maximum extent appropriate, children with disabilities, including children in pubic or private institutions or other care facilities, are educated with children who are not disabled, and special classes, separate schooling, or other removal of children with disabilities from the regular educational environment occurs only when the nature and severity of the disability of the child is such that education in the regular classes with the use of supplementary aids and services cannot be achieved satisfactorily. (Sec 612, (a)(5)(A) IDEA, 1997).

The consideration of the LRE variable in the appropriate education equation has proven to be one of the most challenging and continuously changing professional requirements. Even the language and concepts have changed markedly in the past 10 years, from *mainstreaming* to *inclusion*. The program and philosophical initiatives reflected in the Regular Education Initiative speak directly to this change.

The current issue related to LRE involves *inclusion*, meaning the practice of including students with disabilities in general education classes. Education in the LRE, or *mainstreaming*, has in the past meant that students with disabilities were placed in general education classes only after assignment in special education and only if their skills suggested they could succeed when "cast into the mainstream" (Prasse & Martin, 1996). One effect of mainstreaming has been the exclusion of students with moderate or severe disabilities, and those students with acting-out or oppositional behaviors from participation in general education classes in large part because they were unable to participate at the same rate as their peers (Prasse & Schrag, 1999).

More recent inclusion efforts are based on the needs of the whole student and not exclusively on academic performance as contrasted with that of the mainstream students. Inclusive schooling involves the student attending the school he or she would normally attend if he or she did not have a disability, and with age or grade general education placements occurring without on-site, self-contained classes. Inclusion is based on including students in general education classes and bringing special education services in the form of supportive services to the student, rather than pulling students with disabilities from general education classrooms. In other words, the default program/placement for a student with a disability is the general education program.

While inclusion of students with disabilities in general education classrooms appears to have recently attracted professional attention, the expectations for this practice are long-standing. The Supreme Court, in its first examination of the IDEA, found: "The Act requires participating states to educate handicapped children with nonhandicapped children whenever possible" (*Rowley*, p. 202). The Ninth Circuit previously found the "Congressional preference for educating handicapped children in classrooms with their peers is made unmistakably clear" (*Dept. of Educ. State of Hawaii v. Katherine D.* p.817, 1983). The Third Circuit found to deny "access to a regular public school classroom without a compelling educational justification constitutes discrimination" (*Tokarcik v. Forest Hills School District*, p. 458, 1982).

Because Congress, through legislative action, adopted the ruling in right-to-education cases (e.g., that students with disabilities had the right to access the same program and activities as students without disabilities), Congress declared that students with disabilities must be educated with students without disabilities to the maximum extent appropriate. To make sure that students were not segregated in order to receive services, and that those integrated students were not left to fend for themselves in classrooms designed for the education of students without disabilities, Congress required that supplemental aids and services for students with disabilities be made available within the regular classroom.

The central program and legal question is whether the services needed in the segregated (or more restrictive) environment could be feasibly provided in a nonsegregated setting. "If they can, the placement in the segregated school would be inappropriate under the Act" (*Roncker v. Walter*, p. 700, 1983). *Oberti v.*

Board of Education (1993) at the trial level made the point even clearer that schools cannot refuse to place special services in regular settings:

> The IDEA requires school systems to supplement and realign their resources to move beyond those systems, structures, and practices which tend to result in unnecessary segregation of children with disabilities (p. 1333).

In the past few years, the courts have rendered important decisions that focus inclusion questions, further interpret those sections of IDEA that bear heavily on the LRE mandate, and support IDEA reforms that reinforce programming in general education classes, rather than differential diagnosis and categorical placement. Recent court decisions constitute a trend that is supportive of program reforms that bring resources to students, rather than students to resources.

The first court decision to deal with what is referred to as the LRE was *Roncker*, in 1983. In 1987, the Eighth Circuit considered the issues in *A.W. v. Northwest R-1 School District* (1987), and the Fifth Circuit Court of Appeals adopted a standard for the questions that would be asked in *Daniel R.R. v. State Board of Education* (1989). The *Daniel R.R.* standard built on *Roncker*. Also, in 1989, the Fourth Circuit added its analysis in *Devries v. Fairfax County School Board* (1989). Two years later, the Eleventh Circuit adopted the *Daniel R.R.* approach in *Greer v. Rome City School District* (1992). In 1993, the Third Circuit Court of Appeals in *Oberti* adopted the *Daniel R.R.* approach. In 1993 the Sixth Circuit restated its *Roncker* position in *Doe v. Bd. Of Educ. of Tullahoma City Schools* (1993). The District Court in *Board of Education v. Holland* (1992) adopted the *Daniel R.R.* and *Greer* approaches and reasoning. So, this brief review establishes the import precedent set by *Daniel R.R.*

Subsequent to Daniel's parents' challenge to his educational placement, the Fifth Circuit Court of Appeals ruled that Daniel's appropriate placement was full-time special education. The two-part test, as the court reasoned, for determining compliance with the LRE was as follows:

> First, we ask whether education in the regular classroom, with use of supplemental aids and services, can be achieved satisfactorily for a given child. If it cannot and the school intends to provide special education or to remove the child from regular education, we ask, second, whether the school has mainstreamed the child to the maximum extent appropriate (p. 1048).

Daniel R.R. focused the question of inclusion within the legal parameters established by the IDEA and established one set of criteria against which actions, taken by schools regarding program decisions for students with disabilities, would be judged.

Drawing on the criteria set forth in *Daniel R.R.*, the court in *Board of Education v. Holland* (1992) faced the question of whether or not a nine year old who is moderately retarded should be placed full-time in regular education classes, as was recommended by a hearing officer. In reaching its decision, the court recognized the IDEA's emphasis on individualized needs and considerations:

> Thus the decision as to whether any particular child should be educated in a regular classroom setting, all of the time, part of the time, or none of the time, is necessarily an inquiry into the needs and abilities of one child, and does not extend to a group or category of handicapped children (p. 878).

The court's decision in *Holland* was guided by factors relevant to determining if a placement is appropriate and established by federal appellate courts:

1. The educational benefits available to the child in a regular classroom, supplemented with appropriate aids and services, as compared to educational benefits of a special education classroom.

2. The nonacademic benefits to the handicapped child of interaction with nonhandicapped children.

3. The effect of the presence of the handicapped child on the teacher and other children in the classroom.

4. The costs of supplementary aids and services necessary to mainstream the handicapped child in a regular classroom setting (p. 878).

The court's decision found that the school district did not demonstrate that its proposed placement (half day in regular education) would satisfy the legal requirement of educating Rachel Holland to "the maximum extent appropriate" with her nonhandicapped peers. The school district failed to demonstrate that "placement in special classes will provide equal or greater educational benefits to Rachel" (p. 882). In short, the school district failed on all four of the above-mentioned criteria, and the court affirmed the recommendation of the hearing examiner.

Oberti v. Board of Education (1993) confronted most of the same issues that were raised in *Daniel R.R.* and *Holland*. Drawing heavily on the criteria set forth in *Daniel R.R.*, the Third Circuit Court of Appeals identified three factors that must be considered in deciding whether a child can be educated satisfactorily in a general education classroom with supplementary aids and services:

1. What steps has the school taken to try to include the child in a general education classroom.

2. Is a comparison made between the educational benefits the child will receive in a general education classroom (with supplementary aids and services) and the benefits the child will receive in the segregated, special education classroom.

3. What is the possible negative effect the child's inclusion may have on the education of other children in the classroom.

In this case, the appellate court affirmed that the school district did not meet its burden of proving that Rafael Oberti could not be educated satisfactorily in a general education classroom with supplementary aids and services.

Similarly, a federal district court in *Mavis ex.rel. Mavis v. Sobol* (1994) found that the school district failed to make a reasonable attempt to accommodate the student in the general education classroom with the support of supplementary aids and services. The district had no records to support regular education efforts, subsequent to identifying the student as disabled. With no documentation to support efforts in the general education classroom (meaning monitoring a student's progress as supplementary aids and services are provided), the district was in no position to argue that the student was unable to function in the general education classroom.

The issues were similar in *Corey H. v. Chicago Public Schools and the Illinois State Board of Education* (1998), only in this situation it was not only a school district that was challenged regarding inclusion and the LRE requirement, but a state department of education as well. Plaintiffs argued that children with disabilities in the Chicago Public Schools were segregated and placed in unequal educational environments as determined by their category of disability, not by their individual need. The Chicago Public Schools reached a consent agreement with the plaintiffs whereby the Chicago Public Schools would bring between one-third to one-half of its 553 schools into compliance with IDEA's LRE mandate within an 8-year period. The Illinois State Board of Education (ISBE) did not agree to a settlement, and their case went to trial. The Federal District Court held ISBE in violation of IDEA due to its failure to ensure that placement decisions were based on a student's individual needs as determined by the IEP. The court was direct in its judgment of the ISBE stating, "Unfortunately, and inexplicably, the ISBE continues to deny the undeniable and defend the undefendable (sic.). The 'case' it presented at trial was unpersuasive and unsupported by the facts and the law"(p. 901). The court ordered the ISBE to implement statewide procedures to identify and correct LRE violations, inform teachers and administrators of their responsibilities regarding educating children in the LRE, change the certification code and standard to comply with a LRE mandate (i.e., move away from categorical certification), and change the state funding formula to be consistent with the LRE mandate and the requirements set forth in IDEA 1997.

Not all decisions have determined regular classroom settings as the appropriate program. *Poolaw v. Bishop* (1994) supported the district claim that the least restrictive environment for a student with a hearing impairment who did not read or write was the state school for the deaf. In *MR v. Lincolnwood Board of Educ., District 74* (1994), the school district argued that the appropriate program for a student with an emotional disorder was a therapeutic day school. The court agreed with the school district. Finally, when considering the appropriate placement for a 15-year-old diagnosed with ADHD and Tourettes Syndrome, the Ninth Circuit ruled an off-campus self-contained program was the appropriate placement (*Clyde K ex.rel. Ryan K. v. Puyallup Sch. Dist.*, 1994). Of significance is that in each of these three cases, the school district was able to provide ample evidence documenting the efforts which had been extended in the general education setting.

The judgment of an appropriate education is then a complex and changing issue. The fundamental constitutional, legislative, and judicial requirements allow for the delineation of some general practice considerations, including:

1. IEP's are created by a team (professionals and parents).

2. The process followed by the team is an important legal consideration in judging the appropriateness of the school-based decision.

3. The content of the IEP is equally important, either from the perspective of what is stated, what is not stated, and what is missing that should be stated.

4. Programming must proceed on the basis of what is articulated in the IEP.

5. There must be measurable goals and objectives for each student and evaluation of a student's progress is required so that results are realized, not just services provided.

6. Parental participation is absolute at every stage.

7. Appeal of school district decisions is permitted first through the administrative hearing process and second through the court. Appeals may be based on either alleged procedural violations or alleged content/substance violations.

IDEA PROVISIONS SUPPORTING NONCATEGORICAL PROBLEM SOLVING DELIVERY SYSTEMS SUPPORTING BEST PRACTICES

There are several provisions of IDEA 1997 and the accompanying regulations (1999) that support noncategorical program delivery and problem-solving approaches rather than categorical pull-out deficit models of programming.

Findings and Purposes

In the findings that serve as the basis for the IDEA Amendments, Congress stated:

> Over 20 years of research and experience has demonstrated that the education of children with disabilities can be made more effective ...(F) providing incentives for whole-school approaches and pre-referral interventions to reduce the need to label children as disabled in order to address their learning needs; and (G) focusing resources on teaching and learning while reducing paperwork and requirements that do not assist in improving educational results (Section 601(c)(5), IDEA).

The IDEA Amendments explicitly places an emphasis on student outcomes, rather than paperwork and a previous emphasis on the process from identification, assessment, eligibility determination, program planning, and program implementation. This marks a legislative shift away from special education procedures that have been seen as almost an *end* rather than a *means to an end*. A focus on outcomes (as opposed to classification and diagnosis) will help focus on student needs rather than categories or labels.

Funding Provisions

IDEA 1997 states that "nothing in this Act requires that children be classified by their disability as long as each child who has a disability listed in Section 602 and who, by reason of that disability, needs special education and related services is regarded as a child with a disability under this part" (Sec 612 (a) (3) (B) IDEA, 1997). Although a previous federal policy, rather than explicit language in the law, this new provision within IDEA explicitly allows states to pursue noncategorical funding systems and programs without the *perceived* dilemma of generating funds through reporting within disability categories.

Other funding provisions within the IDEA Amendments support the implementation of noncategorical eligibility, placement, and programming practices. School districts may use funds received under IDEA to carry out schoolwide programs under the Elementary and Secondary Education Act. This allows school districts to explore program options that are noncategorical, are coordinated closely with other federal and state-funded programs provided within individual schools, and are part of an integrated educational whole (e.g. coordinated closely with the overall general education program).

In addition to allowing the use of Part B (special education) funds for the support of schoolwide programs, these funds may benefit children without a disability if the IEP for a child with a disability is being carried out in the regular class or other education-related setting. This provision codifies an existing federal policy that allows for limited provision of incidental benefits to students without disabilities who may be participating in activities related to IEPs of students with disabilities.

School districts may also use up to 5% of federal funds generated under IDEA 1997, in combination with other funds, to develop and implement a coordinated service system designed to improve results for children and families. This provision supports functional approaches, such as noncategorical services, and to explore problem-solving strategies for the coordination and integration of education, health, mental health, and social services (Sec 613(f)(2), IDEA, 1997).

Evaluation Procedures

A full and individual evaluation is required to determine if a child has a disability and to determine the educational needs of the child. A variety of assessment strategies and tools (including information provided by the parent) must be used to gather relevant, functional, and developmental information that may assist in determining (a) whether the child is a child with a disability and (b) the content of the individualized education program, including information related to allowing the child to be involved and progress in the general curriculum, or preschool children to participate in appropriate activities.

Tests and other evaluation materials used to asses the child must be selected and administered so as not to be discriminatory on a racial or cultural basis and provided and administered in the child's native language or other mode of communication, unless it is clearly not feasible to do so. Although criteria are provided for any standardized tests that are given to a child, the IDEA does not require standardized tests to be used. Curriculum-based assessment, functional analysis of behavior, and structured classroom-based observation are appropriate assessment strategies and techniques. In fact, the law requires a review of existing evaluation data as a component of an initial evaluation. The law requires a review of existing evaluation data "including evaluations, and information provided by the parents of the child, current classroom-based assessments and observations, and teacher and related services providers observations." Continuing, "on the basis of that review, and input from the child's parents, identify what additional data, *if any*, are needed to determine whether the child has a disability" (emphasis added). It is clear that the team has an option of not collecting additional data if it believes the existing database is sufficient. Assessment tools and strategies must provide relevant information to directly assist persons in determining the educational needs of the child (Sec. 614 (b)(d)(A-D), IDEA, 1997).

Eligibility Determinations

The Congressional intent for the IDEA Amendments of 1997 is that labeling of students by type of specific disability is not required. The evaluation and eligibility determination provisions specifically support approaches that focus on curriculum and learning rather than on remedial intervention approaches following the assignment of a disability categorical label. The law requires a variety of assessment tools and strategies to gather relevant functional and developmental information, including information provided by the parent to determine if a child has a disability (general, rather than specific category) and the content of the child's IEP. It is clear that Congress intends for the use of functional information that provides relevant information to directly assist persons in determining the educational needs of the child. In the past, the "at least perceived" necessity to label students with an eligible funding disability created an unintended outcome of testing for this purpose rather than for obtaining relevant information to guide and inform curriculum and instructional decisions (Sec 614(b)(3)(D), IDEA, 1997).

Link to the General Education Curriculum

There are a number of provisions within IDEA that emphasize the integration and coordination of special and general education. A Congressional finding within IDEA is that over 20 years of research and experience has demonstrated that the education of children with disabilities can be made more effective by (a) having high expectations for such children and ensuring their access to the general curriculum to the maximum extent possible; (b) strengthening the role of parents and ensuring families have meaningful opportunities to participate; (c) coordinating IDEA with other state and federal school improvement efforts such that special education can become a service for children rather than a place where they are sent; (d) providing appropriate special education and related services and aids and supports in the regular classroom whenever appropriate (Sec. 601(c)(5), IDEA).

Individualized Education Program

The IEP provisions of IDEA support maximum participation of students with disabilities within general education. Specifically, IEPs must contain a statement of how the disability affects the child's involvement and progress in the general curriculum. In addition, there must be measurable annual goals and benchmarks or short-term objectives related to meeting the child's needs resulting from the child's disability that will enable the child to be involved with and progress in the general curriculum. This required link to the general curriculum supports functional, classroom-based approaches, rather than a medical model that has, in the past, focused on remediation of deficiencies often unrelated to the general education curriculum (Sec. 614(d)(A (i-viii), IDEA).

The IEP team must also consider the strengths of the child and the concerns of the parents for enhancing the education of their child. This strength-based emphasis is compatible with assessment and eligibility strategies that are curriculum and instruction oriented rather than based on assessment techniques that identify deficiencies and specific disabilities/deficits.

Access to Records: The Family Educational Rights and Privacy Act

The Family Educational Rights and Privacy Act (FERPA; 1976, also referred to as the Buckley Amendment) was adopted by Congress at the same time it passed the original legislation providing an education for disabled students. Adopted as a result of many complaints from parents and students about record inaccessibility and inaccuracy, the law established rules regarding access and inspection, copying, and release of student records. Many of the requirements were repeated in later legislation (e.g., IDEA). Although the law is more than 20 years old, questions remain and some disagreement over the accessibility of certain records continues.

Questions focus on which records are accessible, which records, if any, are exempt, and how the procedures and principles of confidentiality, privileged communication, and test security relate in any way to the records access law. Frequently the questions focus specifically on accessibility of test protocols and "private notes." The answer to such questions is partially found in the law's definition of a record *and* through a study of congressional intent regarding the law. An education record is defined as follows:

A. For the purposes of this section the term "education records" means, except as may be provided otherwise in subparagraph (b), those records, files, documents, and other materials which
  i. contain information directly related to a student and;
  ii. are maintained by an educational agency or institution, or by a person acting for such an agency or institution.

B. The term "education records" does not include:
  i. records of instructional, supervisory, and administrative personnel ancillary thereto which are in the sole possession of the maker thereof and which are not accessible or revealed to any other person except a substitute.

Where psychologists have questioned the right of parents to access certain records, they usually have referred to Part B above. In claiming that a protocol is not an accessible record, some school psychologists have claimed that a protocol is in their sole possession and that they are the exclusive maker, or that the protocol is a private note.

When the meaning of legislation is unclear the intent may be learned through a review of the congressional debate and/or accompanying statements of explanation. It is here that the intent of the law is found and in this case helps clarify the issue of accessibility of protocols. It is in the Joint Statement in Explanation of Buckley/Pell Amendment (Congressional Record at S.21488, December 13, 1974) that the intent of the definition and exception is partially clarified:

> An individual should be able to know, review, and challenge all information—with certain limited exceptions—that an institution keeps on him, particularly when the institution may make important decisions affecting his future, or may transmit such personal information to parties outside the institution. This is especially true when the individual is a minor. Parents need access to such information in order to protect the interests of their child.
>
> The amendment makes certain reasonable exceptions to the access by parents and students to school records. The private notes and other materials, such as a teacher's daily record book, created by individual school personnel (such as teachers, deans, doctors, etc.) as memory aids would not be available to parents or students, provided they are not revealed to another person, other than in the case of a substitute who performs another's duties for a temporary period.

Continuing, the statements go on to say:

> If a child has been labeled as mentally or otherwise retarded and put in a special class or school, parents would be able to review materials in the record, which led to this institutional decision...to see whether these materials contain inaccurate or erroneous evaluations about their child.

The Congressional intent is affirmed in *John K. v. Board of Education for School District 65* (1987). This Illinois appellate court decision held that raw psychological test data were part of a student's temporary record subject to disclosure. The school psychologist who had administered the Rorschach argued that the verbatim responses were raw data and not subject to disclosure. The court was not persuaded either by professional standards or by federal regulations that the psychologist cited in support of nondisclosure.

Of relevance to the question of accessibility are the requirements of P.L. 94-142 that provide parents the right to inspect and review their children's records collected, maintained, and used by the school in its special education decision making. It would be difficult to argue that tests used by psychologists and test results are not used in this process and are therefore inaccessible. Certainly a parental challenge to placement (either at the hearing or judicial level) would result in a request to review test protocols. To refuse would be to deny parents the right to review important records on which the school's decision was based. Finally, access does not necessarily mean obtaining a copy. With respect to test protocols, publishing companies have made it clear that such material is protected by copyright restrictions. So while parents or their legal representatives might have access, indiscriminate or wholesale copying is not allowed. Clearly the access-to-records requirements necessitate a delicate balance between the public right to be informed and the psychologist's responsibilities to the student and accepted professional standards.

SUMMARY

As a profession we have come to experience ongoing changes that affect our practices and procedures. The sources of change come from within and from outside the discipline. The legal influence has been pervasive and constant. As school psychologists we understand the mandates of parental participation, notice and consent, the requirement that all children with disabilities be afforded an education, and the necessity to ensure valid and reliable assessments that address educational needs, not just categorical disabilities. There are constitutional foundations and statutory requirements for these and other practices, and any change in our practice will require adherence to these.

Many of the emerging reforms in school psychology are very compatible with sound legal practice—practice that not only honors the technical requirements of the law but the intent as well. Some examples include:

1. Problem-solving models that are outcomes driven and not dependent on categorical labels are reflective of best practice.

2. Curriculum-based assessment faces fewer problems associated with cultural differences than does norm-referenced assessment.

3. Greater emphasis on classroom-based instruction responsive to the individual needs of disabled students who are educated as a matter of first course with nondisabled students invites (if not demands) integration in the LRE.

4. Meaningful evaluation of short-term objectives and long-term goals increases the likelihood of achievement-oriented results and is more readily accomplished when using curriculum-based assessment.

5. Assessment strategies that are functional and curriculum-based do satisfy the assessment and eligibility requirements of IDEA.

In the end school psychological practice must focus more on strategies and skills that contribute to successful educational interventions for students and less on practices that are aimed primarily at differential diagnosis and categorical programming . The more success we have with the former the less we will need to be concerned about whether or not school psychological services are complying with legal requirements.

Best Practices in Utilizing Professional Ethics

Susan Jacob
Central Michigan University

OVERVIEW

Ethics

The term "ethics" generally refers to a system of principles of conduct that guides the behavior of an individual. A system of ethics is viewed as developing within the context of a particular society or culture. Ethics is composed of a range of acceptable (or unacceptable) social and personal behaviors, from rules of etiquette to more basic rules of society.

The terms "ethics" and "morality" are often used interchangeably. However, according to philosophers, *morality* refers to a subset of ethical rules of special importance. Solomon (1984, pp. 6–7) suggests that moral principles differ from other aspects of ethics in that they are more fundamental, universal, rational, and objective. Ross (1930), a twentieth–century English philosopher, identified a number of moral duties of the ethical person: nonmaleficence, fidelity, beneficence, justice, and autonomy. These moral principles have provided a foundation for the ethical codes of psychologists and other professionals (Bersoff & Koeppl, 1993).

The focus of this chapter is *applied professional ethics*, the application of broad ethical principles and specific rules to the problems that arise in professional practice. Applied ethics in school psychology is thus a combination of moral considerations, ethical principles, and rules that guide the conduct of the practitioner in his or her professional interactions. The present chapter focuses on school-based practice. Bersoff (1999) and Koocher and Keith-Spiegel (1998) provide discussion of issues associated with independent practice.

Sources of Guidance

CODES OF ETHICS

Professional organizations such as the American Psychological Association (APA) and the National Association of School Psychologists (NASP) adopt codes of ethics to protect the welfare of consumers of psychological services and maintain the public trust in psychology. These codes are drafted by committees within professional organizations, and reflect the beliefs of association members about what constitutes appropriate professional conduct. When practitioners violate codes of ethics, they may face sanctions by their professional organization. Adoption of a formal code of ethics also serves to enhance the prestige of the profession, and may reduce the perceived need for external regulation and control.

NASP's *Principles for Professional Ethics* (PPE) (most recently revised in 2000) were developed to provide guidelines specifically for school psychologists employed in the schools or in independent practice. NASP's code focuses on protecting the well-being of the student/client, but also prescribes conduct to protect the rights and welfare of the parent, teachers, and other consumers of school psychological services. The code provides guidelines in the following areas: professional competence; professional relationships with students, parents, the school, the community, other professionals, and trainees and interns; advocacy of the rights and welfare of the student/client; professional responsibilities in assessment and intervention; reporting data and sharing results; use of materials and technology; research, publication, and presentation; and professional responsibilities related to independent practice.

APA's (1992) *Ethical Principles of Psychologists and Code of Conduct* (EP) consists of general principles and specific ethical standards to protect the welfare of individuals and groups with whom psychologists work. APA's code of ethics differs from NASP's PPE in that the EP were developed for psychologists with training in diverse specialty areas (e.g., clinical, industrial-organizational, school) who work in a number of different settings (independent practice, industry, hospitals and clinics, public schools, university teaching and research).

PROFESSIONAL GUIDELINES

Both NASP and APA have developed professional guidelines for the delivery of school psychological services. Professional guidelines differ from codes of ethics in both scope and intent. The guidelines represent a consensus of trainers and practitioners about roles and duties of school psychologists, desirable conditions for the effective delivery of services, and the nature of competent professional practice. NASP and APA seek to ensure that members abide by their respective codes of ethics and will investigate and adjudicate code violations. In contrast, professional guidelines provide a model for excellence in the delivery of quality comprehensive school psychological services, and it is recognized that not all school psychologists or school psychological service units will be able to meet every standard outlined (National Association of School Psychologists, 2000).

Ethical Codes Versus Ethical Conduct

Codes of ethics guide the conduct of the practitioner in his or her professional interactions with others. However, ethical conduct is not synonymous with simple conformity to a set of rules outlined in professional codes and standards (Hughes, 1986). Codes of ethics are *imperfect* guides to behavior for several reasons. First, they are composed of broad, abstract principles along with a number of more specific statements about appropriate professional conduct. They are at times vague and ambiguous. Second, there are often competing ethical principles that apply in a particular situation, and specific guidelines at times conflict with law. In some situations, a primary or overriding consideration can be identified in choosing a course of action; in other situations, no one principle involved clearly outweighs the other (Haas & Malouf, 1989). A third reason ethical codes are imperfect guides in the school setting is that there may be conflicting interests of multiple clients (e.g., pupil, parents, classmates). A fourth limitation of codes is that they frequently fail to address new and emerging ethical issues. Ethical conduct thus involves careful choices based on knowledge of codes and standards and ethical reasoning.

Ethics and Law

Many aspects of school psychological practice are regulated by federal and state law. Law is a body of rules of conduct prescribed by the state that have binding legal force. Failure to comply with law can result in legal action against the practitioner (e.g., malpractice suits) or the school, and possible loss of certification or licensure to practice.

Both NASP and APA codes of ethics require practitioners to know and respect the law. According to Ballantine (1979), ethical behavior must conform with the law, not defy it. Professional codes of ethics are generally viewed as requiring decisions that are "more correct or more stringent" than required by law (Ballantine, 1979, p. 636). Both NASP and APA require practitioners to adhere to codes of ethics when ethical codes establish a higher standard than required by law. When ethical codes and law conflict, psychologists are obligated "to seek to resolve such conflict through positive, respected, and legal channels, including advocacy efforts involving public policy" (NASP-PPE, III, D, #5).

BASIC CONSIDERATIONS

Four Broad Ethical Themes

Concern for the rights and welfare of children is "the top priority" in the delivery of school psychological services (NASP-PPE, IV, A, #4). However, school psychologists typically serve multiple clients including children, parents, teachers, and systems. "When the school psychologist is confronted with conflicts between clients groups, the primary client is considered to be the child. When the child is not the primary client, the individual or group of individuals who sought the assistance of the school psychologist is the primary client" (NASP-PPE, IV, A, #1).

Jacob-Timm and Hartshorne (1998) identified four broad themes underlying ethical choices in school psychology. Their four themes were adapted from ethical principles articulated in the "Canadian Code of Ethics for Psychologists" (Canadian Psychological Association, 1991). The first broad theme was *respect for the dignity of persons* (welfare of client). Consistent with this principle, school psychologists value client autonomy and safeguard the client's right to self-determination (NASP-PPE, III, B, #3; C, #4), respect client privacy and the confidentiality of disclosures (NASP-PPE, III, A, #9, #10,# 11; B, #2; C,# 6), and are committed to fairness and nondiscrimination in interactions with the client and others (NASP-PPE, III, A, #2; D, #3). The second broad principle was *responsible caring.* According to this principle, school psychologists are obligated to work within the boundaries of their professional competence and accept responsibility for their actions (NASP-PPE, II; III, A, #1). The third broad principle was *integrity in professional relationships.* School psychologists are candid and honest about the nature and scope of the services they have to offer and work in full cooperation with other professionals to meet the needs of children in the schools (NASP-PPE, III, A, #3, #4; B, #2; C, #1; E). The fourth broad principle was responsibility to community and society. School psychologists recognize that their profession exists within the context of society and work to ensure that the science of psychology is used to promote the welfare of all school children and to improve schools, neighborhoods and communities (NASP-PPE, III, A, #1; IV, B, #5).

Ethical Decisions

Ethical choices can be made on an intuitive or a critical-evaluate level. Intuitive choices are based on feeling responses to situations along with personal beliefs. Critical-evaluative choices are reasoned. In the provision of psychological services, decision making on a critical-evaluative level is consistent with sound professional practice. A decision is likely to be viewed as ethical if it is based on generally accepted ethical principles, if it is a reasoned outcome of a consideration of the principles, and if it is universalizable to other similar situations (Haas & Malouf, 1989).

Use of a Decision-Making Model

Competent practitioners are committed to a proactive rather than a reactive stance in ethical thinking and conduct (Tymchuk, 1986). They use their broad knowledge of ethical codes, professional standards, and law along with ethical reasoning skills to anticipate and prevent problems from arising. However, not all problem situations can be anticipated or prevented. Use of an explicit decision-making model may help the practitioner make informed, well-reasoned, choices in resolving problems when they do occur. Furthermore, in difficult situations, the course of action chosen may be questioned and challenged. Use of a systematic problem-solving strategy will allow the practitioner to describe *how* a decision was made. This may afford some protection when difficult decisions come under the scrutiny of others (Tymchuk, 1986). A number of ethical decision-making models have been proposed in the literature (see Cottone & Claus, 2000, for a review). An eight-step problem-solving model adapted from Koocher and Keith-Spiegel (1998) is shown in Table 1, and an application of the model is illustrated in the Appendix.

BEST PRACTICES

The remaining portion of this chapter focuses on privacy, informed consent, confidentiality, and ethical issues associated with psychoeducational assessment and intervention.

Privacy and Informed Consent

Privacy has been defined as "the freedom of individuals to choose for themselves the time and the circumstances under which and the extent to which their beliefs, behaviors, and opinions are to be shared or withheld from others" (Siegel, 1979, p. 251). The schoolchild's right to privacy is a legal and an ethical issue. Statutory and case law have recognized the need to balance the interest of the state (school) in fulfilling its duty to maintain order, ensure pupil safety, and educate children, with the personal freedoms and rights generally afforded citizens. Consequently, in the school setting, students do not have the full range

Table 1. **Ethical Decision-Making Model**

1. Describe the parameters of the situation.
2. Define the potential ethical-legal issues involved.
3. Consult ethical-legal guidelines, if any, already available that might apply to the resolution of each issue. Consider the broad ethical principles as well as specific mandates involved.
4. Evaluate the rights, responsibilities, and welfare of all affected parties (e.g., pupil, teachers, classmates, other school staff, parents, siblings).
5. Generate a list of alternative decisions possible for each issue.
6. Enumerate the consequences of making each decision. Evaluate the short-term, ongoing, and long-range consequences of each possible decision. Consider the possible psychological, social, and economic costs to affected parties. Consultation with colleagues may be helpful.
7. Present any evidence that the various consequences or benefits resulting from each decision will actually occur.
8. Make the decision. Consistent with ethical codes (APA, NASP), school psychologists accept responsibility for the decision made and monitor the consequences of the course of action chosen.

Note. Adapted from a model in Koocher and Keith-Spiegel (1998, pp. 12–15).

of privacy rights afforded adult citizens, but they are not without privacy protections. A schoolchild has privacy rights with regard to his or her person (body) and personal possessions (U.S. Constitution), education records (Family Educational Rights and Privacy Act of 1974 (FERPA)), and private thoughts, beliefs, and behaviors (the Protection of Pupil Rights Amendment of 1978 and special education law protect privacy by requiring informed parent consent prior to the gathering of certain types of personal information). In addition, state laws may provide additional pupil and family privacy protection.

Respect for client privacy also is an ethical mandate. Consistent with the general principle of respect for the dignity of persons and the valuing of autonomy, school psychologists are obligated to respect the pupil's (or other client's) right to self-determine the circumstances under which they disclose private information. Furthermore, every effort is made to minimize intrusions on privacy (NASP-PPE, III, B, #1). School psychologists do not seek or store personal information about pupils, parents, teachers, or others that is not needed in the provision of services. Practitioners comply with state regulations and district policy regarding safe storage of records, and in determining how long psychological records are retained before disposal. When obsolete confidential information is purged from files, psychologists are obligated to ensure it is shredded or otherwise destroyed (NASP-PPE, III, A, #9; IV, D, #5).

Ethical codes, professional standards, and law are consistent in requiring parent consent (or the consent of an adult student) for school actions that may result in a significant intrusion on personal or family privacy beyond what might be expected in the course of ordinary classroom and school activities (Corrao & Melton, 1988). Consequently, with the exception of unusual situations, informed consent is obtained prior to the provision of psychological services (NASP-PPE, III, A, #4; B,# 2; C, #1). In the delivery of psychological services in the schools, as elsewhere, the three key elements of informed consent are that it must be knowing, competent, and voluntary. Knowing means the individual giving consent has a clear understanding of what it is they are consenting to. Competent means legally competent to give consent. In law, adults are presumed to be competent while minors are presumed to be not capable of making legally binding decisions (Bersoff, 1983). Consequently, consent typically is sought from the parent or guardian of a minor child prior to the provision of services. Parent consent may be bypassed in emergency situations (e.g., student is suicidal), and, in some states, minors may self-refer for psychological assistance independent of parent notice or consent (see discussion below). The third element of informed consent is that it must be voluntary, that is, consent is obtained without coercion or undue enticement. Federal law outlines specific requirements for informed consent for psychological evaluation of students with suspected disabilities (Individuals with Disabilities Education Act of 1990 (IDEA)) and for the release of information from school records (FERPA). To safeguard the right of pupils with disabilities to special education services, IDEA also outlines procedures for schools to follow when parents refuse to consent to assessment of a child with a suspected disability.

Although minors are not generally seen as legally competent to consent autonomously to (or refuse) psychological services in the schools, practitioners are ethically obligated to respect the dignity, autonomy, and self-determination of their pupil-clients. However, at times it is necessary to balance the child's rights to privacy and self-determination against concerns for the welfare of the child. In the delivery of school services, it is ethical to proceed without the child's explicit assent if the service is considered to be of direct benefit to the child. School psychologists do not seek the child's assent if refusal will not be honored (Corrao & Melton, 1988; also NASP-PPE, III, B, #3).

Practitioners have an ethical obligation to inform pupil-clients of the scope and nature of psychological services whether or not children are given a choice about participating in the services (NASP-PPE, III, B, #2). Also, consistent with the principle of respect for autonomy, practitioners permit and encourage pupil-client involvement in intervention decisions (e.g., selection of goals) to the maximum extent appropriate to the child and the situation (Weithorn, 1983). A child's participation in intervention decisions may lead to enhanced motivation for treatment, an increased sense of personal responsibility for self-care, greater treatment compliance, and reduced rates of early treatment termination (Kaser-Boyd, Adelman, & Taylor, 1985; Weithorn, 1983). However, psychologists must guard against overwhelming children with choices they do not wish to make for themselves.

Self-referrals for counseling pose a particularly challenging dilemma for school psychologists. Students who are minors may wish to see the psychologist on the condition that their parents not be notified. Osip (quoted in Canter, 1989) recommends allowing one precounseling screening session without parental permission. This precounseling meeting can serve to ensure the pupil is safe and not in danger. At this time, the school psychologist can discuss the need for parental consent for further counseling sessions, offer to contact the parent on behalf of the student, or offer to meet jointly with the student and parents to discuss consent and ensure ongoing parent support.

In some states, minors are given the right to access to certain types of treatment (usually limited to conditions of a medical nature) without parent notice or consent. School practitioners need to consult their state laws to determine whether minors are given the right to seek psychological treatment independent of parental notice or consent in their state (Corrao & Melton, 1988). If state laws are silent on this issue, then practitioners may wish to work with school administrators to develop a district policy that allows minors to been seen for at least one precounseling session by the psychologist independent of parent notice or consent.

Confidentiality

School psychologists are ethically obligated to "respect the confidentiality of information obtained during their professional work. Information is revealed only with the informed consent of the client, or the client's parent or legal guardian, except in those situations in which failure to release information would result in clear danger to the client or others" (NASP-PPE, III, A, #9). The interpretation of the principle of confidentiality as it relates to the delivery of psychological services in the school setting is a complicated matter. However, one clear guideline emerges from the literature on confidentiality in the school setting. School psychologists define the parameters of confidentiality at the onset of offering services (NASP-PPE, A, #11; Davis & Sandoval, 1982). The parameters of the promise of confidentiality will vary depending on the nature of the services offered.

CONFIDENTIALITY AND DIRECT SERVICES TO THE PUPIL-CLIENT

The provision of direct services to the student means that the practitioner works with the student directly (e.g., individual counseling) and there is little or no collaboration with others. The initial interview with the student/client should include a "direct and candid discussion of limits that may exist with respect to any confidences communicated in the relationship" (Koocher & Keith-Spiegel, 1998, p. 117; NASP-PPE, III, A, #11). Much has been written about the importance of confidentiality for building and maintaining the trust essential to a helping relationship. However, as Taylor and Adelman (1989) have observed, the promise of confidentiality can limit the psychologist's ability to help when the client is a minor child. Consequently, school psychologists must weigh a number of factors in deciding the boundaries of a promise of confidentiality (e.g., age and maturity of the student-client, self-referral or referral by others, reason for referral). Whatever the parameters, the circumstances under which the psychologist might share confidences with others must be clear. Taylor and Adelman (1989) provide suggestions regarding how to create an atmosphere of safety and trust in which the pupil knows and understands the exceptions to the promise of confidentiality, yet is motivated to disclose personal thoughts, feelings, and important information.

In the provision of direct services to the student, there are three situations in which the school psychologist is obligated to share confidential student-client disclosures with others: (a) when the student requests it, (b) when there is a situation involving danger to the student or others (e.g., potential suicide, suspected child abuse or neglect, a student who is a danger to others), and (c) when there is a legal obligation to testify in a court of law (Hummel, Talbutt, & Alexander, 1985). (See "privileged communication" in Jacob-Timm and Hartshorne (1998) for a discussion of the circumstances under which a psychologist must disclose confidential information in a legal proceeding).

Generally, under state statutory law and case law, school personnel have a legal obligation to take steps to ensure the safety of pupils under school supervision. In addition, in many states, therapists have a legal duty to take reasonable steps to prevent anticipated harm when the client is a danger to self or others (e.g., *Tarasoff v. Regents of California*, 1976). Consequently. school psychologists may be legally as well as ethically obligated to disclose confidential information if the disclosure is necessary to protect the client or others from harm (NASP-PPE, III, A, #9). Courts cases (e.g., *Eisel v. Board of Education of Montgomery County*, 1991) have been interpreted to suggest that school personnel have little discretion regarding whether to contact parents once information suggests a potential student suicide. Parents must be warned when there is any reason to believe a pupil has suicidal intentions. Also, when a student is determined to be a threat to another pupil, the intended victim and the parents of the intended victim should be notified. School professionals also are legally required to report suspected child abuse to a child protection agency.

Thus, school practitioners are obligated to share student confidences with others in situations involving potential student suicide or other self-injurious behavior, students who are a threat to others, and suspected child abuse. In addition, students may report any number of behaviors that, although not immediately dangerous, have the potential to be so (e.g., substance abuse, eating disorders, risky sexual behaviors). Determining an appropriate course of action in such situations can be difficult. However, if it becomes apparent in working with a student-client that confidentiality must be broken, the decision to divulge confidential information should be discussed with the student-client if possible.

Confidentiality and Collaboration

School psychologists may provide direct services to the student-client. However, they typically work in collaboration with teachers, parents, and others to assist the student, a situation that complicates the translation of the principle of confidentiality into appropriate action. In collaboration, the individuals involved generally carry joint responsibility for assisting the pupil, and information to assist the student will most likely be shared by those involved in the collaborative effort. At the onset of offering services, the psychologist needs a clear prior agreement about confidentiality and the limits of confidentiality with those involved in the collaborative effort (NASP-PPE, III, A, #11; B, #2; C, #6). If information received in a confidential situation is subsequently disclosed in order to assist the teacher or parent in meeting the needs of a student, it is recommended that *only generalizations, rather than specific confidences*, are shared (Davis & Sandoval, 1982; also NASP-PPE, III, A, #10). Furthermore, generalizations are shared with others involved in the collaborative effort only if those generalizations "are essential to the understanding and resolution" of the student's difficulties (Davis & Sandoval, 1982, p. 548). For example, it is not appropriate to disclose a child's list of reasons why the child dislikes a new step-parent; however, it may be helpful to disclose that the child is experiencing difficulty adjusting to a new family situation along with exploring strategies to facilitate adjustment.

Confidentiality and Teacher Consultation

In providing consultation services, the school psychologist works with a teacher or another school professional to aid in professional functioning (e.g., classroom management). The parameters of confidentiality must be discussed at the onset of the delivery of services, and, at a minimum, teachers should clearly understand what and how information will be used, by whom, and for what purposes. The psychologist also should have a prior agreement about those parameters with others in the school setting (NASP-PPE, III, A, #11).

In general, in consultation with the teacher or other school staff, the guarantees of client confidentiality apply to the consultant–consultee relationship (Fanibanda, 1976). All that is said between the psychologist and consultee is kept confidential by the psychologist, unless the consultee requests information be disclosed to others (Davis & Sandoval, 1982). Violation of confidentiality in consultation with teachers or other staff is likely to result in a loss of trust in the school psychologist and impair his or her ability to work with the consultee and others.

In providing consultative services to teachers, ethical responsibility requires that limits to the promise of confidentiality be identified. Thus, for example, the practitioner may want to ensure a prior agreement that the consultant may breach confidentiality in those unusual instances when the consultee "chronically and stubbornly" persists in unethical activities (Conoley & Conoley, 1982, p. 216). However, "Before breaching confidentiality, the consultant must have expended all resources at influencing the consultee to take collaborative action" (Hughes, 1986, p. 491). Such a breach of confidentiality should be given careful consideration, and would only be appropriate when the consultee's actions are harmful or potentially harmful to students. "The consultee's approach toward the client actually must be detrimental to the child rather than a less than optimal approach" (Hughes, 1986, p. 491). The consultant is obligated to discuss the need to disclose confidential information with the consultee prior to disclosure.

Psychoeducational Assessment

School psychologists are trained to be knowledgeable of the multiple factors that affect learning and behavior. As pupil advocates, they work with teachers and others to remedy pupil learning and behavior problems in the classroom prior to seeing a child for psychological assessment. As Messick (1984) has noted, ethically, a child should not be exposed to the risk of misdiagnosis unless deficiencies in instruction have first been ruled out.

Five broad ethical-legal concerns emerge from an analysis of ethical codes, professional standards, and federal laws that address psychological assessment: Psychologists must strive to ensure that psychoeducational evaluations are ***multifaceted***, ***comprehensive***, ***fair***, ***valid***, and ***useful*** (Jacob-Timm & Hartshorne, 1998).

MULTIFACETED

Psychoeducational assessment of a child with learning or behavior difficulties must be based on a variety of different types of information from different sources. Practitioners "use multiple assessment methods such as observations, background information, and information from other professionals, to reach comprehensive conclusions" (NASP-PPE, C, #3). No decisions should be made on the basis of a single test score. Primary emphasis is given to scores and information from the most reliable and valid sources in interpretation and decision making. Diagnostic hypotheses are confirmed or abandoned by collecting additional information that verifies (i.e., cross-validates) or disconfirms the hypothesis (Kaufman, 1994).

COMPREHENSIVE

Children with learning or behavior difficulties should be assessed in all areas related to the child's difficulties, including, if appropriate, health, vision, hearing, social and emotional status, cognitive abilities, academic performance, communicative status, and motor abilities.

FAIR

In the selection of assessment tools, psychologists strive to choose the most appropriate instruments and procedures in light of the child's age, gender, native language, disabilities, and socioeconomic, cultural, and ethnic background (NASP-PPE, IV, C, #1). Evaluation procedures must be selected so that a child with disabilities is not penalized on measures of cognitive ability, achievement, and adaptive behavior because of failures owing to disability. When students have limited English proficiency, language proficiency information should be gathered and used to guide the selection and interpretation of assessment tools.

Ethical codes, professional standards, and special education laws also mandate *nonbiased* assessment of children from minority cultural, ethnic, and racial backgrounds (NASP-PPE, IV, C, #1). Practitioners are obligated to evaluate research evidence indicating whether a test or procedure is equally valid when used with children from differing ethnic backgrounds, and choose the fairest and most appropriate instruments available (Reynolds, Lowe, & Saenz, 1999). In order to minimize bias in administration, interpretation, and decision making, school psychologists must be keenly sensitive to culture and ethnicity as factors that impact on behavior (American Psychological Association, 1993). Furthermore, if testing and assessment practices result in children from a particular ethnic group being placed in inferior programs, then the outcomes or consequences of testing are biased and unfair (Reschly, 1997).

VALID

The *Standards for Educational and Psychological Testing* (Standards) (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 1999) provide guidelines for psychologists and educators to use in evaluating whether their tests and assessment procedures meet acceptable technical standards. Evaluation of the technical adequacy of assessment instruments and procedures involves consideration of the evidence for test reliability, validity, and the adequacy of the standardization norms. School psychologists are obligated to select tests and other evaluation procedures that meet high professional standards and are valid for the purpose for which they are used (NASP-PPE, IV, C, #2). They are also obligated to ensure instruments are administered and interpreted by qualified examiners in a manner consistent with sound professional practice (NASP-PPE, IV, C, #5).

USEFUL

Evaluation instruments must be selected to provide a profile of the child's strengths and difficulties to aid in instructional planning. The assessment is planned to ensure the information gathered will result in maximum feasible assistance to the child (NASP-PPE, IV, C, #2, #7).

School psychological assessment often results in the assignment of a formal diagnostic label. Legally and ethically, practitioners are obligated to ensure that when labels are assigned they are based on valid assessment procedures and sound professional judgment. When labels are used, "The least stigmatizing labels, consistent with accurate representation, should always be assigned" (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 1999, p. 88).

The school psychologist shares findings through the written report and in conferences with the parent, student, and teacher. In accordance with FERPA, parents have access to psychological reports. Consequently, the writer must take into account the fact that reports will be read by professionals and nonprofessionals. Reports should emphasize recommendations and interpretations rather than a simple passing along of test scores (NASP-PPE, IV, D, #3).

This section focused on ethical-legal concerns associated with psychoeducational assessment of individual pupils. Readers may wish to consult Jacob-Timm and Hartshorne (1998) for a discussion of ethical-legal issues associated with school testing and assessment programs, and see Ysseldyke, Nelson, and House (2000) and the Standards (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 1999) for guidelines pertinent to participation of students with disabilities in statewide and district-wide testing programs.

Intervention

In recommending interventions, psychologists strive to propose a set of options for consideration by the parents, student, and others involved in intervention decision making (NASP-PPE, III, C, #1, #5). The proposed options should consider all resources (school and community) available to assist the student and family; and take into account the objectives of the school and classroom, the support and assistance that can be made available to the teacher, and the values and capabilities of the parents (NASP-PPE, III, C, #1, #3, #5).

School psychologists recommend intervention techniques "that the profession considers to be responsible, research-based practice" (NASP-PPE, IV, C, #4). Furthermore, psychologists offer to provide only those services that are within the scope of their own competence and training. If needed interventions are not within their realm of expertise, then the practitioner enlists the assistance of other specialists in a supervisory, consultative, or referral role (NASP-PPE, II, A, #1). Consistent with the ethical principle of responsible caring, school psychologists monitor (or assist in monitoring) the effectiveness of the interventions selected, and "modify or terminate the treatment plan when the data indicate the plan is not achieving the desired goals" (NASP-PPE, IV, C, #6).

In recent years, the use of behavioral assessment and intervention techniques has gained popularity in the public schools, in part because of changes in special education law (IDEA). In accordance with the 1997 amendments of IDEA, if a student with disabilities is subject to a disciplinary suspension from his or her regular placement for more than 10 days, then the Individualized Education Program (IEP) team must modify the student's behavior plan (if he or she has one) to address the problem behavior. If the student does not have a behavior plan, then the IEP team must conduct an assessment to determine the function the behavior serves (a functional behavioral assessment (FBA)), and design a behavior intervention plan based on the FBA. The following paragraphs consequently focus on special concerns associated with the problem clarification and intervention stages of behavioral interventions for students with problem behaviors. Readers interested in ethical-legal issues associated with other types of interventions (e.g., counseling, psychopharmacologic) may wish to consult Jacob-Timm and Hartshorne (1998), Bersoff (1999), or Koocher and Keith-Spiegel (1998).

An ethical concern that arises during the problem clarification stage is whether the goals of intervention are in the best interests of the child. Classroom behavior modification programs introduced in the late 1960s often focused on teaching children to "be still, be quiet, and be docile" (Winett & Winkler, 1972), what Conoley and Conoley (1982) later referred to as "dead man behaviors." Such goals may assist the teacher in maintaining a quiet, orderly classroom, but they are not likely to improve learning or foster the healthy personal-social development of children (Winett & Winkler, 1972). The psychologist and teacher are ethically obligated to select target behaviors that enhance the long-term well being of the child and are consistent with the long-range goal of self-management. Goals must be selected to ensure that the pupil will develop appropriate adaptive behaviors and not just suppress inappropriate ones.

During the intervention stage, school psychologists are ethically obligated to select (or assist in the selection of) change procedures that have demonstrated effectiveness. Practitioners also are obligated to select the least drastic procedures, and those that minimize the risk of adverse side effects, that are likely to be effective (NASP-PPE, I). There is some consensus in the literature about the procedures that are the most acceptable, and those that are least acceptable in the schools. First-choice strategies are based on differential reinforcement (e.g., reinforcing appropriate behaviors incompatible with problem behaviors). Second-choice strategies are based on extinction (withdrawing of reinforcement for undesired behavior). Third-choice strategies include removal of desirable stimuli (e.g., time-out procedures). The least acceptable (fourth choice) strategies are those that involve presentation of aversive stimuli.

The courts have scrutinized the use of behavioral interventions with schoolchildren. Such methods must not deprive pupils of their basic rights to food; water; shelter, including adequate heat and ventilation; sleep; and exercise periods. Time out is a popular intervention strategy, and the courts have found its use in the schools to be permissible. However, practitioners are ethically obligated to ensure time out is used in a manner that safeguards the rights and welfare of pupils. More specifically, school personnel must monitor a secluded student to ensure his or her well being, the time-out room itself must not present a fire or safety hazard, the door must remain unlocked, and students must be permitted to leave time out for appropriate reasons. Students should be given prior notice about the types of behaviors that will result in being placed in time out, and school personnel must ensure that time out, when used as punishment, is "not unduly harsh or grossly disproportionate" to the offense (*Dickens by Dickens v. Johnson County Board of Education*, 1987, p. 158). The court in *Dickens* noted that "prolonged, uninterrupted confinement" in time out might be a violation of a pupil's legal rights (his or her liberty interests and right to education) (p. 159). Creating a time out by segregating or secluding the child within the classroom, or requiring the child to do schoolwork while in the time-out room, is recommended (*Dickens*, 1987). Furthermore, as behavioral experts have cautioned, the length of the time out should be appropriate for the child's age and developmental functioning.

A highly controversial issue in the schools is the use of aversive conditioning, where a discomforting stimulus is presented contingent upon the child's undesirable behavior. Aversive therapy should only be considered in the treatment of behaviors that, if allowed to continue, would have far worse consequences than the therapy (e.g., self-biting, head banging, or other seriously maladaptive behaviors). It is typically considered to be a last resort strategy, legally permissible and ethically appropriate only after all else has failed (Jacob-Timm, 1996). Green (1990) developed guidelines to follow to ensure behavioral interventions, particularly those involving aversives, are safe and humane, respectful of individual rights and dignity, and used only in ways likely to benefit the student (also see Repp and Singh, 1990).

SUMMARY

Ethical choices in professional practice are best made on a critical-evaluative level. Decisions made on a critical-evaluative level involve thoughtful consideration of general ethical principles and professional codes of ethics. A decision is likely to be viewed as ethical if it is based on generally accepted ethical principles, if it is a reasoned outcome of a consideration of the principles, and if it is universalizable to other similar situations.

Four broad ethical principles pertinent to the delivery of school psychology services were identified. The first was respect for the dignity of persons. Consistent with this principle, psychologists value client autonomy and safeguard the client's right to self-determination, respect client privacy and the confidentiality of disclosures, and are committed to fairness and nondiscrimination in interactions with the client and others. The second broad principle was responsible caring. According to this principle, practitioners are obligated to work within the boundaries of their professional competence and accept responsibility for their actions. The third broad principle was integrity in professional relationships. According to this principle, psychologists are candid and honest about the nature and scope of the services they have to offer and work in full cooperation with other professionals to meet the needs of children in the schools. The fourth broad principle was responsibility to community and society. School psychologists recognize that the profession exists within the context of society and work to ensure that the science of psychology is used to promote human welfare.

In addition to these broad principles, practitioners should be familiar with the more specific principles and rules outlined in NASP's *Principles for Professional Ethics* and APA's *Ethical Principles of Psychologists and Code of Conduct.*

School psychologists with a sound knowledge of ethics are likely to anticipate and prevent ethical problems from arising. However, not all problem situations can be anticipated or prevented. Use of an explicit decision-making procedure may help the practitioner make informed, well-reasoned, choices in resolving problems when they do occur.

A textbook on ethics and law specifically written to meet the needs of the psychologist in the school setting.

Koocher, G. P., & Keith-Spiegel, P. (1998). *Ethics in psychology* (2nd ed.). New York: Oxford University Press.

A text that discusses the ethical issues psychologists encounter in a variety of practice settings, research, and teaching. The book focuses on the American Psychological Association's (1992) *Ethical Principles of Psychologists and Code of Conduct* and may be particularly helpful for practitioners in independent practice.

National Association of School Psychologists. (2000). *Professional conduct manual*. Bethesda, MD: Author. Available:

Contains both the *Principles for Professional Ethics* and the *Guidelines for the Provision of School Psychological Services*. Required reading for practitioners and supervisors of school psychological services.

APPENDIX: APPLICATION OF AN ETHICAL DECISION MAKING MODEL

The following paragraphs illustrate the thinking of a fictitious school psychologist as the psychologist applies an ethical-legal decision-making model to a problem situation:

1. Describe the parameters of the situation.

When I stopped in the high school office after lunch to pick up my mail and messages, I noticed Brad, a 15-year-old special education student, in the principal's office, visibly upset and agitated, and the principal, Mr. Scott, on the phone. Brad is a learning-disabled student who has a history of emotional problems, including impulsivity, depression, and threats of suicide. The secretary informs me that Brad has just been suspended from school because he harassed another student and then threatened the teacher who reported the incident. The secretary goes on to say that Mr. Scott has "had it with Brad," and is calling for transportation to take him home immediately even though she has been unable to contact the parents and there is no one at home.

2. Define the potential ethical-legal issues involved.

Concern for protecting the welfare of students is my top priority in providing services.I'm worried that if Brad is sent home upset and unsupervised, he may harm himself or others.

3. Consult available ethical-legal guidelines; consider broad ethical principles as well as specific mandates.

No time to consult guidelines, but I know:

- School discipline is the principal's responsibility; school discipline is not my job.
- Students are my primary responsibility, and I am ethically obligated to advocate for their well-being, even if such advocacy creates conflicts with school administrators.
- School district policy requires parent contact before students are sent home for disciplinary reasons.
- The district's safe school plan requires assessment of an individual pupil if he (or she) makes threats to self or others, or is suspected to be a danger to self or others.

4. Evaluate the rights, responsibilities, and welfare of all affected parties.

- To ensure Brad's safety and the safety of others, Brad should be helped to calm down before he goes home, and he should be evaluated to determine whether he poses a threat to himself or others. Outcome of the evaluation will determine the most appropriate course of action (e.g., it may be necessary to have Brad's parents to come to school for a conference and to pick him up).
- Brad's parents have a right to be notified of the situation as soon as possible.
- Although the principal has the authority to suspend Brad, he is violating district policy if he sends Brad home prior to parent notification and prior to a threat assessment. The principal puts himself and the school at risk for a lawsuit if Brad is sent home unsupervised and there is injury to Brad or others.

5. Generate a list of alternative decisions possible for each issue.

- I can respect the principal's decision and do nothing.
- I can intervene by asking the principal to talk with me privately about Brad's situation as soon as he is off the phone.

6. Enumerate the consequences of making each decision.

7. Present any evidence that the various consequences or benefits resulting from each decision will actually occur.

- If I do nothing, then Brad will go home to an empty house, and perhaps nothing will happen. I know, however, that school suspension is sometimes a trigger for suicide or acting out among troubled youth. If Brad expresses his anger by harming himself or others, then the psychological and emotional costs to all will be unacceptably high.
- If I intervene, then it may impair my working relationship with the principal, because he may feel his authority and judgment have been challenged and that I have overstepped the boundaries of my job role.

8. Make the decision.

Even though it is uncomfortable for me, I will intervene. I will discuss the reasons why sending Brad home to an empty house is not advisable, and remind the principal that parent contact is required prior to sending a student home for disciplinary reasons. I will ask to conduct a threat assessment of Brad in accordance with the district's safe school plan.

Note. Model adapted from Ethics in Psychology (2nd ed.), by G. P. Koocher and P. Keith-Spiegel (1998, pp. 12–15). Situation adapted from *Armijo v. Wagon Mound Public School Board*, 159 F.3d 1253 (10th Cir. 1998).

Best Practices in Applied Research

Timothy Z. Keith
Alfred University

OVERVIEW

Why bother with a chapter on research? Conventional wisdom is that school psychologists are not interested in conducting research, and that many are antagonistic toward research. Yet my experiences teaching, conducting workshops, and writing about research lead me to believe that the conventional wisdom may be conventional, but not wise. I have talked to many school psychologists who are indeed interested in conducting research in applied settings, and to many more who want to do a better job of incorporating others' research into their daily practice. Both of these are appropriate research roles for school psychologists. This chapter will examine three hierarchical research roles for school psychologists and discuss the skills needed to fulfill those roles.

For the purpose of this chapter, research is defined as activities designed to produce new scientific knowledge or to use that knowledge to improve school psychological practice. I see three hierarchical research roles for school psychologists:

1. All school psychologists should strive to be competent *consumers* of research. The populations we serve, our methods and our instruments, and our roles are constantly changing. At the same time, there are always plenty of bandwagons tempting us to hop aboard. The best way to stay abreast of current developments while avoiding bandwagons is the careful reading of research. Research tells us which good ideas really *do* work.

2. There is also a need for a smaller number of school psychologists to act as *distributors* (or synthesizers or disseminators) of research. They may read research relevant to a topic of interest and summarize and draw conclusions from it for other interested groups, such as other psychologists or a Board of Education.

3. Some school psychologists are interested in performing the role normally considered research: *conducting* research of interest to themselves, their colleagues, or their employers.

The three roles are hierarchical because one needs to be an effective consumer of research to summarize and distribute research effectively, and one needs to be able to summarize research to be an effective conductor of research.

As an example, consider three school psychologists interested in the effectiveness of study skills instruction. John, a research consumer, is interested in study skills instruction as an educational intervention for a low-achieving child. He reads research to find out if study skills instruction is generally effective in improving achievement, which methods of instruction are available, and whether some methods are generally more effective than others or whether some methods are more effective with children similar to the one with whom John is working. Elaine, a research distributor, is asked by her superintendent to investigate whether it would be worthwhile to teach study skills to incoming high school students and, if so, which approach would be most effective. Finally, Carolyn conducts research comparing the achievement of students in her district who were taught study skills to the achievement of children who were not taught such skills.

BASIC CONSIDERATIONS

The Consumer of Research

Although social science research is often contradictory, research is also the one way we have of putting aside our hopes and prejudices and testing whether or not an intervention is effective. To serve children well, psychological practice needs to be consistent with research findings. Yet research is contradictory, and much research is of poor quality and limited applicability. School psychologists thus need to evaluate the research they read in order to separate the wheat from the chaff.

To evaluate research, we should ask two essential questions: Did the research demonstrate anything, and is it applicable to my situation? The training needed to become a competent consumer of research is not extensive and is probably included in most specialist-level school psychology programs. Basic statistics, research, and measurement courses are needed, but those courses should focus on a *conceptual* at least as much as a numerical understanding. Unfortunately, many such courses continue to be taught as if most students were going to be conducting research rather than reading and evaluating it; more attention is needed toward the *evaluation* and use of others' research. Single-case research methods also need more coverage. This is one research method that all practitioners can use, but its coverage is spotty. The primary resource needed by consumers of research is access to relevant journals.

The Distributor of Research

Although all school psychologists should strive to incorporate research results into their practice, all do not need to integrate and distribute research to others or to conduct research; and whether one wants to become a distributor or conductor of research should be a matter of choice and job description.

Distributors of research first need to be good consumers of research, and they additionally need experience sifting through and integrating research findings that may be rather diverse and inconsistent. Their formal training should also include, at minimum, basic courses in research, statistics, and measurement, and guided experience in integrating and summarizing research is probably at least as important. All doctoral and many specialist-level psychologists should have this level of training and at least some experience, at minimum, when writing a thesis or dissertation.

Research distributors need access to a wider range of journals and other sources of research: conferences at which research is presented, the ERIC Document Reproduction Service, and Psychological Abstracts. Electronic databases such as ERIC and PsycInfo—to be discussed in more detail later in this chapter—can enhance greatly the effectiveness of research distributors by providing the ability to search a broad range of journals. Access to a university library is also extremely useful.

The Conductor of Research

It is well known that not all school psychologists are interested in conducting research, but this role should—and often is—available to psychologists with the appropriate interest and training. Again, these roles are seen as hierarchical; we need to be competent distributors of research in order to be good conductors of research, because the conclusions drawn from previous research should guide our own research efforts.

The formal training of those who plan to conduct research needs to be more extensive, and should include a series of research methods and statistics courses. Nevertheless, most doctoral level and some specialist-level psychologists have completed such coursework. Thus, your interests and experiences may determine whether or not you take on this role more so than your previous coursework. Probably the best training for this role is to assist someone else in several research projects or to conduct several research projects under supervision (in addition to a thesis or dissertation). A graduate research assistantship or some sort of research apprenticeship can be extremely valuable.

The conductor of research needs access to the same resources as the distributor of research: research publications and a good library. In addition, most psychologists who conduct research need access to a computer with a good statistical analysis program.

Program Evaluation

Although relatively few school psychologists may be interested in the conducting and publication of research, many more should be interested in the related skill of program evaluation. Schools, clinics, hospitals, and other agencies develop and implement programs on a regular basis, but efforts to evaluate the effectiveness of those programs are all too irregular. Program evaluation is badly needed, and school psychologists are often among those most capable of providing that evaluation. I simply note here that program evaluation falls under the category of conducting research; the skills required for effective program evaluation are the same as those needed to be an effective conductor of research.

BEST PRACTICES

Consumers

READING AND EVALUATING RESEARCH

Consumers of research read and evaluate research as a means of improving their practice. In order to perform this role we must, of course, have access to relevant studies. Consumers must also be able to evaluate the research they read. Much research in the social sciences is contradictory, and an effort to find the empirical answer to a question of practice can be quite frustrating. I do not believe this inconsistency means that research cannot inform our practice. It does mean, however, that evaluation of the research is necessary.

Journals, the primary source of research, accept only a fraction of the articles that are submitted for publication, thus supposedly ensuring that published research is of high enough quality to deserve our trust. Nevertheless, much research, even that published in good journals, is not good research. Research problems are poorly conceived or are trivial; samples are small and poorly selected; inappropriate statistics are used, or mistakes are made in calculating and reporting statistics; research designs are weak and do not rule out plausible alternative hypotheses; designs neither fit the purpose of the study nor test the hypotheses the researcher wants to test. Even when research is well-conceived and conducted, there are problems of interpretation. Most researchers have been guilty of overblown conclusions that extend well beyond what might reasonably be concluded by the results, but more subtle problems are common as well. It is not unusual, for example, for a discussion to address a different issue than that addressed by the design! This problem is common when there is a mismatch between the intended purpose of the research and the research as actually conducted. For all of these reasons, much research is of marginal quality, and consumers need to evaluate carefully the research they do read.

Fortunately, we do not have to be a statistician to evaluate research. Instead, what is needed is a conceptual understanding of research methods and what those methods can tell you. What is the purpose of a representative sample? Of random assignment to groups? When is research experimental and when is it non-experimental? What threats to validity does a multiple baseline design control? What does statistical significance mean? What does analysis of variance, or multiple regression, or factor analysis tell us? Being able to answer these conceptual questions will help us evaluate research much more so than being able to calculate t-tests by hand. We also need to read research articles carefully—even skeptically.

Research evaluation focuses on a number of different aspects of the research, but there are three very important considerations. First, are the internal features of the research conducted well enough so that we can have confidence in the results? The consideration is generally referred to as internal validity (Campbell & Stanley, 1963), but may also be thought of as the "power" of the research design (Keith, 1988). In other words, is the research design powerful enough so that we can be confident that it was the *treatment, and not something else*, that caused a change in behavior?

Second, how generalizable or applicable are the results? This consideration—external validity—focuses primarily on the subjects and treatments used in the research. Are the people participating in the research study similar to those we might encounter during normal practice? Are the treatments used similar to those we might use in applied settings, or have they been modified drastically to fulfill the requirements of the experiment? There is often a trade off in these two aspects of research. For example, a school-based study in which various classes were assigned differing amounts of homework would likely be less powerful (more threats to internal validity) than a lab-based experiment in which college freshmen were assigned randomly to groups and given different amounts of time to study nonsense words. On the other hand, we would probably feel more comfortable generalizing the results of the first study to a middle school student who does not complete his homework. The second study is more powerful but less generalizable.

Third, is the article written well enough so that readers can understand what was done and the implications of the results? It does not matter how technically sophisticated research is if the writing is unclear and confusing.

Although skepticism is necessary in evaluating research, it should not be carried to an extreme. Be warned: *No research is perfect!* Conducting research consists, in large part, of making decisions and compromises, and there are weaknesses in any piece of research. When we evaluate research we need to weigh its strengths and weaknesses and decide whether the results obtained are trustworthy, whether the treatment described really resulted in the observed behavioral change. On evaluation we will find some research in which the weaknesses are insurmountable, and the results suspect; these studies should be ignored. The rest will fall along a continuum from merely adequate to excellent. We can apply those that are strong in all areas with more confidence than we can those with many weaknesses.

Table 1 includes a list of questions that may be useful in evaluating research articles (see also Cone and Foster, 1993, chap. 7, or Isaac and Michael, 1995, chap. 9). Various sources that may be useful in gaining a conceptual understanding of the issues involved in research are listed in the annotated bibliography.

For research that is well-conducted and well-described, the next problem is application. It is obviously easier to apply applied research than research that is highly theoretical. Intervention studies and psychometric research are often directly applicable to daily practice. But basic and theoretical research may also be quite applicable, especially if it helps us understand how or under what conditions a treatment (or intervention) may be useful. Basic research comparing the effectiveness of various mnemonic devices for different types of subjects might be quite applicable to a student with poor memory skills, for example.

Table 1. Questions for evaluating research articles

- Is the purpose well defined?
- Is the literature adequately summarized?
- Does the introduction establish the need for the study?
- Is the research design appropriate? Is it powerful enough so that you can trust the results?
- Does the research design fit the purpose?
- What type of research design is used (experimental, quasi-experimental, non-experimental, single-case, etc.)?
- Does the analysis fit the design?
- How was the sample collected? Is it representative of the population? Is it large enough to allow a good statistical test?
- Is there evidence to support the reliability and validity of any tests or questionnaires used?
- Are the results presented consistent with the purpose, the design, and the analysis?
- Does the discussion flow from the results? Is it consistent with the purpose of the study?
- Are the conclusions consistent with the results, or do they go well beyond them?
- Are the limitations of the research discussed?
- What are the major strengths and weaknesses of the study?
- Is the article well written?
- Are the results of the study generalizable to your population? Are the treatments generalizable into interventions?
- Is this research applicable to your work?

Note. These questions provide an overview of those aspects that may be important in evaluating research articles. They will not all be equally applicable for all articles.

The connection is not as direct, but a good mix of applied and basic research may be very useful in understanding a problem.

SOURCES FOR CONSUMERS OF RESEARCH

The primary sources of research reports are journals with relevance to school psychology. A useful list of journals with relevance to school psychology is presented in many introductory school psychology textbooks. Conferences, conference proceedings, and the ERIC Document Reproduction Service are other outlets for relevant research, but these manuscripts are generally not as carefully reviewed as are those submitted to journals, so consumers of research need to be even more critical than with journal articles. Research reviews and book chapters are another good source for both consumers and distributors of research. This volume and *Children's Needs II: Development, Problems, and Alternatives* (Bear, Minke, & Thomas, 1997) provide good starting points for many topics. If well done, reviews and chapters provide a concise, objective summary of research knowledge in an area, and their reference lists also provide good listings of the original research. These sources may also provide a good conceptual introduction that will be useful when reading the original research. But like all research, the quality of reviews and chapters varies considerably; you should have some familiarity with at least some of the original articles so that you can be sure that the writer of the review did a competent job of summarizing the research.

If most school psychologists are to be research consumers, rather than conductors, then their concern when taking research courses should be for a conceptual understanding of research. I believe there is one exception to this rule: All school psychologists should be able to develop basic single-case research designs. In my opinion, school psychologists do not need to conduct complex single-case research (although such research is often more applicable to applied settings than are many other types of research), but knowledge of such designs is useful because they can be used to evaluate the effectiveness of virtually *any intervention*—behavioral or otherwise.

AN EXAMPLE: USING RESEARCH TO DEVELOP AN INTERVENTION

As an example, a school psychologist is referred a fifth-grade boy, Sam, who is having trouble keeping up with his peers. The teacher does not think Sam is a candidate for special education, but does want assistance in helping him deal with what appears to be a relatively mild learning problem. Assessment and a review of records support the teacher's suspicions; that is, Sam has never been a star student, but he has never experienced serious problems before either, and has never been referred previously. He appears to have slightly below-average abilities and achievement in a generally high-achieving school. Assessment also suggests that Sam, his teacher, and his parents are all fairly motivated and will be willing to cooperate with some sort of intervention.

The school psychologist has read several articles recently on the effects of homework, and it occurs to her that homework might provide the basis for a cooperative home/school intervention. A cursory review of research suggests that homework is fairly effective for this age group, especially when it is commented on by the teacher and when current homework demands are small (e.g., Keith & DeGraff, 1997). Further investigation reveals that the teacher currently assigns little homework, and thus a homework intervention seems a likely possibility. Additional reading suggests worthwhile features of effective homework interventions (Miller & Kelley, 1991)

The psychologist begins conducting Curriculum-Based Assessments in Reading (e.g., Shapiro & Elliott, 1999) and charting Sam's weekly quiz grades in math and spelling. In cooperation with the teacher and the parents, she plans a homework intervention: The parents will provide a quiet place for Sam to study at a regular time each day; and the teacher will eventually provide daily, individualized homework in at least two of the three areas being charted, and will check the homework, comment on it, and provide feedback to the parents about Sam"s homework accuracy on a daily basis. The parents, in turn, will provide reinforcement at home for homework that meets an agreed upon, adjustable criterion of accuracy (as reported by the teacher).

Because the psychologist wants to ensure it is the intervention, rather than some other, uncontrolled influence that causes any subsequent change in Sam's achievement, she designs the intervention as a multiple baseline design across school subjects. Homework in reading is introduced first, although performance in all three areas continues to be charted. If the intervention is effective, then she might expect to see improvement in reading after a few weeks of the homework intervention while spelling and math grades stay at about the same level. Homework could next be introduced in spelling and, after progress was shown, in math. Of course, if the homework seemed effective in reading, then the teacher and parents might be tempted immediately to begin homework in the other two areas, but they would need to be cautioned against jumping the gun. By conforming to the multiple baseline plan, the psychologist can feel confident that it is the intervention, and not something else, that is causing any change in Sam's behavior. This knowledge is important because it provides information that may be useful in future interventions with Sam and with other students and because it ensures that Sam, his parents, and his teacher are not completing all of this additional work for no purpose. This approach has the added benefit of introducing the intervention gradually and of providing data that may be used to make needed changes in the intervention. The approach is not a sophisticated single single-case design, but it would provide evidence of the effectiveness—or lack of effectiveness—of the intervention. The example also illustrates the intimate connections among research, assessment, intervention, and evaluation. It should also be noted that a wide range of outcome measures (behavioral and otherwise) are possible in single single-case designs. For example, if we were interested in the teacher's impressions of Sam's preparation for class, then we could assess this possible outcome by using a simple rating scale. These daily ratings of preparedness in the three subjects would also fit well in the multiple baseline design.

IMPROVING SKILLS: CONSUMERS

Most school psychologists have had the necessary training to become effective *consumers* of research; what they need is to improve and use these skills. The books and articles in the annotated bibliography may help refresh that training, and they approach research more from a conceptual than a numerical level. Consumers should also read research regularly and attend research presentations at conferences. We school psychologists should be interested in the results of research, but always approach it skeptically. As Reynolds, Lowe, and Saenz (1999, p. 549) reminded us, our attitude should be, "In God we trust; all others must have data."

Of course, if school psychologists are to be effective consumers of research, their employers must recognize this as a part of the job. In my experience, most employers are pleased when their psychologists try to base their practice on solid research, provided that the knowledge (a) does not cost a lot of extra money and (b) is not used as a weapon with which the psychologist battles policies of the administration (as in, "*Well, the research says this program the superintendent started up last month is not very effective.*"). As with any new role, it may be necessary to start this process through an investment of one's own time rather than the employer's; when you can show some payoff—as through effective interventions—your employer will be much more willing to recognize the value of the research consumer approach.

Distributors

INTEGRATING RESEARCH FINDINGS

Distributors of research consolidate and integrate research findings in order to draw conclusions and make recommendations based on those conclusions. To do so, distributors first need access to a body of research, and a wider access than do consumers of research. Distributors need to be able to define their research topic so that their review is neither too broad nor too narrow. I find it helpful to organize research topics as a group of overlapping circles or ovals. For example, if I were interested in the effects of inclusive classroom settings on general education middle school students' math achievement, then I would be most interested in research that directly addressed that question, and I would want to read and evaluate that body of research as comprehensively as possible. Thus, my central topic—and the area of quadruple overlap (marked with the number 1) in Figure 1—is research addressing the effects of inclusion on general education, middle school students' math achievement.

I would also be interested in several related topics, such as the effects of inclusion on other academic areas, the effects of inclusion on the achievement of all students, and other influences on the math achievement of general education middle school students; those topics are represented by the areas of double overlap of the circles (marked 2, 3, and 4, respectively). Although each of these related topics is of interest, they are less central to the main topic of interest, and therefore my reading of research in these

Figure 1. Topics included in a review of the effects of inclusion programs on the mathematics achievement of middle school, general education youth. The farther the topic is from the area of central overlap, the less extensive the review.

areas would not need to be as comprehensive. Much of my information about these topics could even rely on review articles, if they were well done, comprehensive, and recent. Next I would focus on the individual circles (e.g., effects of inclusion) outside the areas of overlap; such topics might receive only a cursory review. Likewise, I would also address other, related areas, such as the design of inclusion programs. Thus, although my reading of the research should cover all important aspects of the problem, I would also spend less time on that research that was less central to my research question.

Like consumers, distributors of research need to be able to evaluate the research they read. In fact, this skill is even more important for distributors because they need to cover the research more thoroughly and are therefore more likely to encounter contradictory findings. Distributors need to weigh better research more heavily in making conclusions. That is, they should base their conclusions primarily on the better research, only using the medium-quality research when it addresses important questions unanswered by better conducted studies.

Probably the most difficult part of consolidating research is *integrating* diverse research findings. The least useful review of research is one that simply lists in separate paragraphs the findings of each research study. Instead, the goal of a research review should be to combine and *integrate* the various research findings in order to draw one or several conclusions (with appropriate caveats) from the research. One rule of thumb is to avoid making the *researchers* the subject of a sentence or a paragraph, but rather to focus on the *findings* of research and make most citations to researchers parenthetical. For example, I might write that "coursework appears an important influence on student learning (Anderson, 1991), whether learning is measured by test scores (Sanchez, 1998) or by grades (Jones, 1997)." This sentence integrates the findings of three hypothetical studies. In contrast, I might have written: "Sanchez (1998), in a regression analysis of 867 high school students, found that the coursework taken by those students had a strong effect on their subsequent achievement test scores. Jones (1997) studied students in academic versus general high school tracts and found that ...." and so on. The first method integrates the findings; the second method treats them separately.

Likewise, the written review should rarely be a chronological presentation of the findings of research. The integrated presentation of studies should be organized in a logical fashion so as to lead to and reinforce the appropriate conclusions. This does not mean that there is one perfect way of organizing a particular review of literature, but some potential formats are certainly more effective than are others. To decide on the proper structure, some writers suggest listing each finding (with citation) on a note card and sorting the cards into different stacks to evaluate alternative organizations (Sternberg, 1993). I find that a table, summarizing the details, findings, strengths, and weaknesses of each study is often useful. Such tables can also be a helpful part of the written review.

Quantitative research synthesis, or meta-analysis, is becoming increasingly common and can be a valuable tool for research distributors. Even those who do not use the quantitative methods of meta-analysis can profit from a discussion of the considerations necessary for valid research synthesis (e.g., Wolf, 1986).

The steps listed above as important in distributing research are identical to the steps involved in a literature review: review an appropriate body of research, integrate the findings, and make conclusions. Distributors of research need to take this process one step farther, however. They are presumably conducting a research review because they wish to bring research findings to bear on some practical problem; they also are conducting the review to share with others. As a final step in such a review, a research distributor should be able to make recommendations for action based on the conclusions.

SOURCES FOR DISTRIBUTORS OF RESEARCH

Research distributors need a wider access to journals and other sources of research than do most consumers. In addition to school psychology journals, distributors need access to journals from educational psychology, special education, and behavioral, counseling, and clinical psychology. Distributors also need access to other sources of research (e.g., conference papers abstracted in ERIC, books) and they should be able to integrate basic, theoretically oriented research with applied research.

Fortunately, the legwork required of research distributors—conducting searches of the literature, finding relevant articles and books—is becoming easier and easier, thanks to the internet and computers. Most university libraries now have internet or CD-ROM access to databases of research articles. Although there are many such databases, ERIC and PsycINFO are probably the most relevant, and include abstracts and publication information from education and psychology journals. It is very easy to search multiple journals quickly for keywords of interest; the results of the search can then be downloaded to disk or printed. Obviously, these new instant searches can be a great starting place for research distributors.

Much of the work involved in distributing research can be completed before a visit to the library. Research distributors can search the holdings of most university libraries in the United States (and many outside the United States) from their home or office using the Internet. School psychology websites may provide good avenues for further investigation. ERIC is available at no charge (e.g., through the U.S. Department of Education website). Although PsycInfo is not free to the general public, it should be available to those with a university affiliation. Many universities with PsychInfo also have it available to anyone who can visit the library itself. Keep in mind that such searches usually produce only abstracts; you still need to get the actual articles of interest. For many, a trip to the university library will be the easiest way to get these. While there, you should talk with a librarian to find out what resources are available in the library itself and online.

For those without a nearby university, ERIC may be the best starting point. As I write this, members of the American Psychological Association (APA) can get access to PsychInfo and to the full text of articles in APA journals through the APA website, although there is a charge for the service. There are also services available (e.g., the Carl UnCover document delivery service or ISI document solution) that will fax or mail you the full text of articles from most academic journals. The services are not cheap, however; as this is written, charges for these services are $10 or more per article, plus copyright fee. Again, contact with a university library for more information will be worthwhile for research distributors interested in such services. These developments in technology are exciting, but please remember that electronic resources are changing rapidly. These internet sites and electronic services may change considerably by the time you read this.

IMPROVING SKILLS: BECOMING A RESEARCH DISTRIBUTOR

Psychologists interested in improving their research distributing skills may also profit from the books and articles listed in the bibliography. Research distributors should also develop the practice of critically reviewing the research they read, and should study research reviews written by others. One excellent way to practice reviewing research is to serve as a referee for articles submitted to journals. Most journal editors are eager to find colleagues who are willing to serve as occasional reviewers for research and review articles submitted for publication in their journals, and editors of school psychology journals are often especially eager to find *practitioners* willing to review articles. Most journals use anonymous reviewing (the reviewer does not know the identity of the author) in order to ensure honesty in reviews; courtesy should not be sacrificed as a result of anonymity. Serving as a reviewer provides practice and often feedback; most editors send each reviewer the comments of the other reviewers in addition to their own blinded letter to the author.

Without realizing it, most psychologists hear questions amenable to research review constantly, from parents, teachers, and administrators. *Do you think young boys should wait an extra year before starting kindergarten? Should I give homework to second graders? Does ability grouping harm low-achieving students? Should we institute a cooperative learning program in the elementary schools?* All of these questions address educational topics that have been the focus of research, and answering those questions is easier with a solid understanding of what research says about the effectiveness of the programs in question. Psychologists who wish to add the role of research distributor to their jobs can begin by volunteering to help provide answers to questions of interest to their school district or other employer, or by volunteering to serve on policy-making committees. For example, district-wide policies on homework are becoming popular; a psychologist serving as a research distributor could provide valuable information to a policy-making committee on the effects of homework on student learning.

Conductors

DESIGNING AND CONDUCTING RESEARCH

Conductors of research first need to be competent consumers and distributors of research. Beyond that, they of course need to be competent in research design and analysis. Arguably, they also need another, often overlooked skill: They should be able to transform vague questions of practice and policy into general research questions. In my experience, the most common mistake made by inexperienced researchers is the tendency to focus immediately on the details of a study (the sample, the statistics to be used); a common mistake made even by experienced researchers is vague or poorly defined research questions. The missing step in both cases is to go beyond the vague questions that led to an interest in the topic being studied and to derive *general, testable* research questions. Do you wonder what can be done to best educate disadvantaged youth, or whether low-achieving first graders should be retained? These vague questions of policy can be phrased as research questions in a variety of ways, each of which would lead to a slightly different research design. I find it helpful to force myself to phrase these vague questions as questions of 10 words or less, usually in the form of does x affect (or improve, or influence) y? *Does grade retention improve later achievement? Does an academic curriculum affect disadvantaged students' future economic success?* Once the general question has been phrased, conducting research is simply a matter of making choices (*How do we define disadvantaged?*) and compromises (*Should we use a small, but intensively interviewed local sample, or a larger regional sample with less information per person?*). With practice, you will find research questions popping up everywhere—as a result of normal conversations, articles in journals, newspaper stories and editorials, and other unlikely sources.

Conductors of research also need competence in a variety of research designs in order to ensure that the design chosen indeed tests the appropriate research question. *Expertise* in research design is not necessarily needed if you are willing to collaborate or seek the advice of someone with that expertise, but a broad understanding of research design is needed. In particular, competence is needed in research methods that are appropriate in applied settings, but which may not be stressed in a typical graduate program: quasi-experimental, single-case, and non-experimental designs, along with psychometric methods.

Similarly, conductors of research need a general, broad competence in analysis in order to ensure that the method of analysis is congruent with the research design and the research question. For any sort of statistical analysis access to a good statistics computer program is needed. There are a multitude of programs available for personal computers, ranging from simple to complex and from cheap to expensive. Reviews of programs are one source for help in choosing a program, and appear occasionally in both professional journals and computer magazines. Beyond reviews, look for a program that computes the statistics wanted, is easy to use, is widely used, and is regularly revised.

One option is to use one of the major, comprehensive statistics packages (e.g., JMP, SAS, SPSS, SYSTAT). These programs are widely used and regularly updated, and errors in the programs will be quickly spotted and remedied. Unfortunately, these packages also tend to be the more expensive and largest programs available. Statistical programs are increasingly becoming required purchases in statistics classes, and are often available at a considerable discount through such classes; the opportunity to purchase a good program at a low cost may be an extra benefit for anyone planning to take a new or refresher research class. For example, as of this writing, the SPSS "Grad Pack" is available for approximately $170 through many university bookstores for registered students, whereas the same set of programs (although with additional documentation) can cost well over $1000 for non-students.

Other options are also available. There are numerous less well known, but comprehensive packages available (e.g., Number Cruncher Statistical Software, NCSS), or programs that add statistical routines to common spreadsheet programs (e.g., Analyse-it for Excel). Such programs tend to be less expensive than the major packages, and many even allow you to download a trial version from their websites. For those who need statistical software only occasionally, there are even web-based statistical packages (e.g., WebStat at the University of South Carolina). These are only examples; many other resources are available. Of course, if you use a specialized or less-common program, you will need to ensure that its results are accurate.

Conductors of research also need competence in communicating the findings of research orally and in writing. Nothing spoils a good piece of research faster than a report that is poorly written, vague, or full of jargon.

IMPROVING SKILLS: BECOMING A RESEARCH CONDUCTOR

Many psychologists have the knowledge necessary to conduct research, and most have, or could easily have, access to data that would be useful for research purposes. School psychologists are awash in data—test scores, ratings, observations—much of which would be ideal for research purposes with a little prior planning. What is generally missing is *practice* doing research; even school psychologists who have completed a thesis or dissertation often do not feel comfortable with the process of doing research. If this assessment is correct, then what psychologists need—those with the necessary requisite skills—is to work with, or even serve as apprentices to, others who actively are conducting research.

Probably the easiest way to develop a research apprenticeship is to contact faculty in school psychology or related areas at a local university. Most graduate faculty are expected to carry on a program of research as a part of their jobs; most would welcome help in data collection, analysis, writing, and the other tasks of research, especially so if you can provide a source of data and are interested in answering research questions that are of interest to them. Another option is to work with others at a local level who are doing research. For those interested in serving as an apprentice, proximity is important in order to experience all aspects of research. For those who already have research experience and who are looking for research collaboration, proximity may not be as important. With the use of attachments to e-mail, long distance collaboration is increasingly easy and common.

The best way to have the role of conductor included as a part of your job description is essentially the same as for a research distributor: volunteer to find the answer to a research question that evolves from a problem facing your school system (or mental health center, etc.). Helping to evaluate new or existing programs may also provide an entree into the role of a research conductor. If your research will answer a question of interest to your employer, not cost a lot of money, and not interfere with your other responsibilities, then you will probably be welcome to conduct it. It may take a commitment of your own time in the beginning, but if you can prove your worth as a research conductor, then your employer will begin to see this role as a part of your job.

SUMMARY

All school psychologists should be involved in research, but this does not mean that all should actually *conduct* research. All psychologists need to be effective *consumers* of research; that is, they should be able to critique research that has implications for their practice and incorporate the findings of that research into their practice. A smaller number of psychologists are needed to serve as research *distributors*: They summarize the findings of relevant research and convey those findings to their colleagues and employers. A still smaller number may be interested in actually *conducting* research: They should be able to design and conduct studies that answer research questions of interest to themselves and their employers. It is not particularly difficult to serve in any of these roles, and advances in computers, software, and the Internet have made these research roles available to a much wider audience. As with any new role, the hardest part is getting started.

ANNOTATED BIBLIOGRAPHY

Cone, J. D., & Foster, S. L. (1993). *Dissertations and theses from start to finish: Psychology and related fields.* Washington, DC: American Psychological Association.
This book is full of excellent advice on how to conduct thesis and dissertation research. It is equally applicable for school psychologists who wish to become research conductors.

Huck, S. W., & Cormier, W. H. (1996). *Reading statistics and research* (2nd ed.). New York: Harper Collins.
This fine book is intended primarily for those who want to read and understand the research of others (here called research conductors and distributors). The book also presents useful examples for writing the results of research. It presents statistics and research design from a conceptual standpoint and does a nice job of demystifying research. The first edition included a helpful introduction to single-case designs, which is missing in this second edition.

Kazdin, A. E. (1982). *Single case research designs.* New York: Oxford University Press.
This is one of several excellent books that can serve as both an introduction and a reference text for single-case research methods.

Keith, T. Z. (1988). Research methods in school psychology: An overview. *School Psychology Review, 17,* 508–526.
This article provides a conceptual overview of diverse research methods used in school psychology, with a particular emphasis on understanding the power of different methods for inferring that a research treatment produces an outcome.

Kerlinger, F. N. (1986). *Foundations of behavioral research* (3rd ed.). New York: Holt, Rinehart & Winston.
This is my single favorite book on research. Kerlinger's is primarily a conceptual, theoretical approach, although he does not shy away from numbers. Although there is some unevenness of coverage (single-case designs are not

discussed; the presentation of LISREL is overly enthusiastic), and the book is becoming dated, this is still a very thorough book.

Phillips, B. N. (1999). Strengthening the links between science and practice: Reading, evaluating, and applying research in school psychology. In C. R. Reynolds & T. B. Gutkin (Eds.), *The handbook of school psychology* (3rd ed., pp. 56–77). New York: John Wiley.
Phillips presents a variety of issues pertinent to research in school psychology, written primarily for consumers and distributors.

Best Practices in Supervision of School Psychological Services

S. A. Hunley
University of Dayton
M. J. Curtis
University of South Florida
G. Batsche
University of South Florida

OVERVIEW

Growth in the number of school psychologists nationwide reflects recognition by the school communities that school psychologists make valuable contributions to the mental health and education of children and youth. More schools than ever before are asking for help in dealing with everyday academic and behavioral problems. School psychologists are entering the field with a higher level of training than in the past (Hunley, 1998) and are prepared to handle a wide range of professional requests.

School psychologists provide direct services to students and families, work as members of school-based problem-solving teams, and provide indirect (e.g., consultative) services to teachers, school buildings, and school districts. The school reform movement that began in the 1980s and continues today has resulted in a significant increase in site-based management, participatory governance (e.g., school improvement teams), accountability based on student outcomes, and a general decentralization of services to the school level. As a result, school psychologists in leadership roles find themselves in the position both of supervising professionals from other disciplines (e.g., social workers/counselors) and being supervised by professionals from other disciplines (e.g., building principals) as well as supervising (and being supervised by) other school psychologists. This increase in demand for services, the ability of school psychologists to offer a variety of services across different settings, and the changing organizational/accountability structure of schools, has changed significantly the focus and nature of supervision. Therefore, there arises a need for school psychologists to consider supervision within a broader framework, one that recognizes the reality of practice in a setting in which the organizational structure, demand for program accountability, and focus on outcomes no longer permits a process that is limited solely to clinical supervision by professional peers. In this framework, it is imperative that a new paradigm of supervision in school psychology must be considered.

BASIC CONSIDERATIONS

Research in Supervision

Literature on the subject of supervision of school psychological services has been very limited. The predominant emphasis in published articles has been on direct, clinical supervision of school psychologists for the purposes of professional accountability and development. In their review of the literature, McIntosh and Phelps (2000) identified five major areas of concentration in clinical supervision research. These areas included (a) clinical supervision practices within the field, (b) the congruence of supervision practices with professional standards, (c) the role of supervision within school psychology training programs, (d) the provision of effective supervision, and (e) the evaluation of models of supervision. Further analysis of the studies in the research by McIntosh and Phelps (2000) lead them to the conclusion that very few were data based and none attempted to demonstrate that supervision led to more effective school psychologists or to more positive client outcomes. The authors call for further research to better understand the efficacy and appropriateness of direct supervision of school psychologists.

The focus in the literature on direct, clinical supervision is understandable given a traditional definition of supervision as a function for ensuring and supporting the accountability and professional growth and development of school psychologist supervisees. However, supervisors are no longer able to limit their responsibilities to that of direct supervision of supervisees for the reasons cited earlier in this chapter. Supervision in school psychology occurs at multiple levels (individual, site/building, and system), by multiple individuals (peers, administrators, unit supervisors), and for multiple reasons (clinical skills, program accountability, student outcomes). Therefore, the basic considerations fundamental to constructing a comprehensive model of supervision must take into account the actual and desired skills of the school psychologist, the expectations of the settings in which the school psychologist provides services (e.g., building or district), and the administrative structures of each of the settings (e.g., principal at school level, supervisor of psychological services at district level).

A comprehensive model of supervision of school psychological services does not suggest the elimination of direct supervision; rather, it expands the concept of supervision to include the roles of non-school psychologists in the process. The comprehensive approach acknowledges that school psychologist practitioners are looking for leadership from a school psychologist who understands their professional practice issues and who can advocate for them at all levels of the system, both directly and indirectly. In addition, the comprehensive approach recognizes that school psychologists will be supervised by other professionals as well. A comprehensive approach provides the leadership to ensure that supervision provided both by school psychologists and other professionals is appropriate for both the tasks and the settings in which the supervision is provided and is fair and equitable to the service provider. As the twenty-first century unfolds, supervisors of school psychologists will be expected to fulfill a much broader role as leaders in the mental health and educational environment of schools.

Supervisors (school psychologists and non-school psychologists) of school psychologists are referred to infrequently in terms of leadership roles. This is incongruent with the fact that they are in an advantageous position to influence the field in its endeavor to provide the best mental health and related educational practices for children and youth in our schools. The time is right for school psychologists to assume a proactive stance in advocating for best services for children and youth in schools and a comprehensive model of supervision and evaluation that supports those best practices. Major reform initiatives, fundamental policy and practice changes, and advancements in technology have opened many doors for change. It has been suggested that major institutional changes within our schools and related mental health organizations reflect the trend toward comprehensive, integrated service delivery (Adelman, 1993). It is logical, therefore, that models of supervision reflect a comprehensive, integrated approach to match the service delivery systems. Supervisors of school psychologists are strategically positioned in schools to be the logical professionals to lead these changes.

Leadership requires active participation in change efforts at the individual, building, and systems levels. The professional functions of the school psychologist practitioner are expanding beyond a narrow emphasis on assessment to include membership on problem-solving teams, the provision of research-based interventions, and crisis prevention and stabilization in the schools. With more responsibility comes a greater need for programmatic planning, organization, and supervision. School psychologist practitioners look to their supervisors for guidance and leadership that will enable them to provide effective services to students in schools. The practitioner will depend more and more on competent supervisors to ensure that school psychological services are relevant and recognized as effective by the consumers of those services.

The school and community members are also searching for support, guidance, and leadership that will ensure that their students and children are properly educated and that our schools provide safe, secure, and healthy environments. School psychologists are charged with improving the mental health and educational success of students. It makes sense then, that supervisors of school psychological services should provide the guidance and leadership necessary to connect students, schools, and community members with the support services that they need.

BEST PRACTICES: A COMPREHENSIVE MODEL OF SUPERVISION IN SCHOOL PSYCHOLOGY—A NEW PARADIGM

Goals of Supervision

Supervisors of school psychological services demonstrate leadership by emphasizing the development and maintenance of a service unit that provides positive, measurable mental health and educational outcomes for children and youth (National Association of School Psychologists, 2000). In addition to the leadership goal, two other primary goals of supervisors of school psychological services have been identified (Harvey & Struzziero, 2000). Supervisors work toward improving the professional functioning of supervised school psychologists. They are also charged with protection of clients the school psychologists serve. In combination, these goals suggest that the supervisor could be viewed as a link between the school psychologists as service providers and the clients they serve.

In this linking role, the supervisor must be responsive to client needs. In the case of school psychological service units that are situated in schools, the clients are defined as those people who may be affected by the services provided by the unit. Those clients include students, teachers and school personnel, administrators, parents, and the community. It is the responsibility of supervisor(s) to provide leadership in the development of a unit that provides mental health and educational support services that are driven by client needs.

Goals for Service Delivery

Service delivery decisions for the school psychological services unit are driven by characteristics of the school district, the mission of the settings in the district within which the school psychologist provides services (e.g., school improvement plan), predetermined job parameters (e.g., assessment for special education, crisis team participation), and accountability or educational outcomes. School districts vary in size, population served, geographic location, and a multitude of other ways that may affect the manner in which school psychological services are delivered. For example, in a large urban district with a high rate of poverty and violence, there may be a great need for strong crisis management services. The school psychological services unit within the district may be large, and organized to include a crisis team that can be mobilized on short notice. On the other hand, a rural district that has a relatively small number of students in a large geographical area may not have the resources within the school psychology unit to provide the same level of crisis management services. In the latter case, the unit may need to include other educators, community resources, and agencies as part of the crisis management team. The supervisor must understand the demographic characteristics of the school district in order to facilitate the development of a service delivery system that not only meets client needs but makes optimum use of the available resources.

School psychological services delivery may be well defined in school districts through clearly articulated mission statements and job descriptions. However, mission statements and job descriptions that are developed at the district level without consideration of the needs of individual school buildings and communities may be incomplete or inappropriate. It is the responsibility of all the supervisors within the unit to be involved in the development of both the district mission statement and the relevant job descriptions and expectations for school psychologists at the practice site levels (e.g., school building or district program).

Two goals are inherent in the development of mission statements and job descriptions from the perspective of school psychological services. First, information must be gathered to determine client needs. Clients needs might vary considerably across the multiple settings in which a particular school psychologist provides services. Second, input regarding the capacity and types of services that can be delivered by the unit are offered. With information from both perspectives an appropriate mission statement and relevant job descriptions can be produced.

A related, but important area of concern with regard to the development of school psychological services is included in the general topic of educational outcomes. For school psychologists and intervention teams, this means the documentation of measurable positive outcomes in the mental health and/or the educational status of the students they serve. More specifically, the focus is on the degree to which intervention services result in a significant improvement in academic performance and/or social behavior in the school setting. Frequently, school psychologists, who are focusing on long-term changes for individual students, may seem to be in conflict with the school district's need to demonstrate overall positive academic gains for the majority of the students, and the teacher's and parent's need to see quick improvement. The supervisors of individuals providing school psychological services should serve to facilitate understanding from all perspectives and promote collaborative efforts to resolve the differences. This can be accomplished in a number of ways. First, school psychologists can provide information to supervisors and consumers that explains the relationship between the intervention and the desired outcomes. Second, school psychologists can provide student-based outcome data that demonstrate that the student is making progress toward the desired goal. It is the responsibility of the school psychologist to provide these links and data. Failure to do so results in a situation in which the supervisor is making judgments about the value of services based on the perception of those services. Decisions are made based on the expectation that the school psychological services unit will demonstrate that services are efficient and effective and that the providers of such services will be held accountable for the results.

Roles and Skills of the Supervisor

The supervisors of school psychological services conduct business through two related approaches. The problem-solving approach is a reactive technique for responding to problem situations that already exist. In contrast, the decision-making approach is a proactive stance that is taken when planning for change. Both approaches require information gathering and the generation of strategies. Reliability and validity of problem solving and decision making are optimal when data are used for defining, planning, monitoring, and accounting for the results generated from each of these strategies. Problem-solving and decision-making skills guide the effective and efficient provision of services. Supervisors use these skills to conduct daily business in all of their professional roles.

Harvey and Struzziero (2000) suggest that there are three basic roles in which supervisors engage. They are interpersonal roles, informational roles, and decisional roles. Interpersonal roles require strong communication skills for organizing, managing, and leading in the delivery of school psychological services to clients. Effective interpersonal communication skills lead to increased productivity and positive outcomes.

The second role of gathering and generating information is most beneficial when it is data based and leads to effective solutions or desirable plans. Information is gathered from the clients and other sources in order to inform the school psychological service unit regarding the determination and prioritization of job tasks. The unit also generates information in order to provide accountability data to clients.

Decisional roles are often administrative in nature and are frequently rooted in accountability issues. Decisional roles include reactive problem-solving as well as proactive decision-making skills. Effective and efficient supervisors generally spend more time in a proactive mode versus a reactive mode. The proactive mode allows the supervisor to predict and minimize potential problems before they become major issues. In effect, the supervisor takes the perspective of a change agent instead of a crisis manager.

Knowledge and skill in a variety of areas is essential for competency in supervision of school psychological services. The National Association of School Psychologists' Supervision, Evaluation, and Accountability Committee (National Association of School Psychologists' Supervision Work Group, 1998) has generated a list of these competencies. They identified a number of areas needed for proficient interpersonal facilitation by supervisors such as competence in consultation, collaboration, and systems change. There also must be a sound understanding of and commitment to ethics, best practices in the delivery of services, professional standards, continuing professional development, the application of accountability methods, models of service provision that are responsive to client needs, sources of funding, and legal and regulatory issues in order to effectively and efficiently solve problems and make decisions. Administrative demands can be streamlined through the use of technology and through the implementation of management and business practices. This requires that supervisors remain abreast of new leadership principles, administrative technologies and advancements in the areas of time management, communication, data management, budgeting, and grant writing.

Comprehensive Model of Supervision

This chapter offers a model for the supervision of school psychological services that emphasizes the role of the supervisor as a leader and a linker. The Comprehensive Model of Supervision is composed of the types of supervision (clinical and administrative) that occur at three different levels (individual, building/program, district/agency). This model expands the focus of supervision from the individual, clinical supervision to one that includes individual and systems-level perspective. The model recognizes further the pragmatic perspective that school psychologists will be supervised by individuals trained in other disciplines and that school psychologists will also supervise individuals from other disciplines.

Re-Defining the Types and Levels of Supervision in School Psychology

TYPES OF SUPERVISION

There are two types of supervision that are relevant to the profession of school psychology today: clinical and administrative. The traditional perspective of supervision in school psychology has remained focused over the years on the process of clinical supervision. *Clinical supervision* is the practice of one professional (presumably with more experience or greater skill level) providing guidance and feedback to another professional *within the same profession.* A great deal has been written on the process of clinical supervision across the mental health professions. Best practices have been developed to facilitate the ongoing professional growth of individuals within a given profession.

The primary purpose of clinical supervision is to ensure that individuals practicing in a profession provide consumers with the quality services expected from professionals who hold a particular credential. The process of clinical supervision is important enough that most professional associations have promulgated standards that define the professional requirements necessary to perform the role of a supervisor and indicators of quality supervision (e.g., number of supervision hours required to obtain a credential). Clinical supervision is generally provided one-to-one or in small groups and focuses on the maintenance and development of the skills that define that profession (e.g., problem solving, consultation, communication). The role of the supervisor is to recognize the need, to support school psychologist practitioner efforts to participate in training opportunities, and to ensure that direct clinical supervision is provided as an avenue for professional development. The extent of direct clinical supervision varies according to the needs of the individual school psychologist. Novice or struggling practitioners require more intensive individual supervision by the supervisor, while more experienced and effective practitioners may benefit from group supervision or peer mentoring. In all cases, the supervisor is responsible for ensuring that appropriate clinical supervision is provided.

A number of methods or approaches have been identified for use in clinical supervision with school psychologists (Harvey & Struzziero, 2000). Among them are the consultation approach, the psychodynamic orientation, the client centered approach, the behavioral approach, the cognitive behavioral approach, and the systems approach. The development of competencies may require the provision of alternative professional development opportunities as well. For example, school psychologists may benefit from external training programs offered by universities, national and state professional organizations, and other agencies. Each method has as its primary goal the improvement and maintenance of individual practitioner skills.

The consultation approach is based on collaborative problem solving relationship between the supervisor and supervisee. In contrast, the psychodynamic orientation focuses on fostering a therapeutic relationship and mirrors the interactive relationship between the supervisee and the client. The client-centered approach emphasizes the development of skills through the direct analysis of content and process of supervisee-client sessions. The behavioral approach promotes the growth of supervisee skills through goal setting, provision of feedback, and monitoring of supervisee behavior. The emphasis in the cognitive behavioral orientation is on changing observable behaviors of the supervisee by modifying cognitions, affect, and actions. No one approach fits all supervisees, and the supervisor must choose the model(s) most appropriate based on the level of competence that is expected to be most effective in addressing the specific needs of that individual.

Administrative supervision in school psychology focuses primarily on processes that relate to how well a unit (e.g., psychology services unit) or building (e.g., particular school) performs. Administrative supervision is focused on outcomes (were goals achieved), group dynamics (did the team perform well as a unit), logistics (were goals completed on time, was follow-up provided), and consumer satisfaction (did teachers/parents/administrators perceive the services in a positive way). There is little or no focus on the professional behaviors associated with the discipline-specific clinical skills (e.g., assessment/consultation) necessary to achieve the desired outcomes. In fact, individuals providing administrative supervision may not have the qualifications necessary to engage in discipline-specific clinical supervision *and may be trained as professionals in another discipline.* An appropriate analogy would be a hospital administrator who is responsible for the administrative oversight of physicians in the hospital but is not a physician and therefore cannot provide clinical supervision to the staff.

Administrative supervision goals may clash with clinical supervision goals. It is not unusual for administrative supervision goals to focus on "efficient" services while clinical supervision goals focus on "quality" services. Efficient services are those that maximize productivity, minimizing the investment of resources. The provision of efficient services can be a point of contention between supervisors and school psychologists for whom they are responsible in school districts that maintain a high priority on productivity. For example, school psychologists may be valued by administrators according to the number of evaluations they complete. On the other hand, the school psychologists may place a higher value on the number and quality of intervention-based services that are completed. The supervisor, in such a district, must link the school district administration with the school psychologists through active, open communication. The perceptions, goals, obstacles, and outcomes generated from each group must be clearly and objectively shared with the other group in order for them to agree to an acceptable definition of efficient services. Once an agreeable definition of efficiency is determined, it is the responsibility of the supervisor to obtain outcome data from each school psychologist. These outcome data are the basis for determination of success in achieving the identified standard, for both the individual school psychologist and the unit. The supervisor then makes decisions accordingly, having the ultimate responsibility for ensuring that services are maximized and costs are minimized.

Effectiveness in the delivery of school psychological services can be more difficult to measure than efficiency. Therefore, a clear definition of effectiveness must be established and agreed upon. Effectiveness includes two basic elements: quality and positive client outcomes. The "quality" of school psychological services is an intangible, subjective concept that can be defined further by identifying measurable outcomes that tend to be process oriented. Quality in this sense might be indicated by less paperwork, less processing time, happier funding sources, general client satisfaction, lower costs, and a positive public image.

Positive client outcomes, the second element of effectiveness, might be demonstrated through the collection of data either from individual cases that focus on intervention-based services or from group or system level benefits for clients. For example, data could be used to demonstrate positive changes in individual student behavior or academic performance following intervention. On the other hand, data might also be used to demonstrate positive changes at the classroom, school, or even district level as a result of school psychological services. The supervisor works with the school psychologists to determine the amount and type of data that will demonstrate the effectiveness of services delivered by individuals, as well as by the unit, and then facilitates data collection. In addition, the supervisor presents the data to the appropriate audiences in order to demonstrate the level of effectiveness and efficiency of the unit.

Clinical and administrative supervision are integral to the development of school psychological services that are responsive to the needs of clients, and are based upon best practices in the provision of school psychological services. In the Comprehensive

Model of Supervision, both types of supervision are included at the individual level. However, clinical supervision is primarily directed inwardly, toward the school psychologist within the unit, as a method for professional development. Conversely, administrative supervision is directed toward external audiences, and serves to promote the success of the unit.

LEVELS OF SUPERVISION

Supervision in school psychology occurs primarily at three levels: individual, building, and unit. Clinical and administrative supervision can occur at all three levels. Figure 1 represents, at a functional level, the possible supervision scenarios considering both type and level of supervision. The school reform movement of the late 1980s resulted in significant changes in the organization and operations of schools. Three major changes that affected supervision of school psychologists were decentralization, participatory governance, and outcome-based evaluation methods. An effective building principal was viewed as the essential ingredient necessary in a successful school. Building principals were given broad authority for staff selection, staff evaluation, and budget administration. Professionals assigned to individual school buildings now had part or all of their supervision and evaluation provided by educational administrators. The organization of individual school buildings was built around committees (e.g., school improvement committee) composed of practitioners (teachers, counselors, school psychologists). These committees were given the charge of "reforming" the school climate, recommending curricular change, and providing leadership for the professional development of the staff in the building based on the perceived needs of the students and families. The implementation of outcome-based evaluation methods has resulted in the "grading" of buildings, public announcement of achievement profiles for buildings, and the expectation that all services in a building contribute, in a meaningful way, to the building "outcome."

As a result of the changes that have occurred in the past 15 years, school psychologists find themselves accountable to different levels of supervision. These include supervision provided by a colleague or mentor, supervision provided by the educational administrator in a building or program, and supervision provided by the administrator of the psychological services unit (who may or may not be a school psychologist). Because supervision does (and will continue to) occur at different levels, it is important to identify the *types* of supervision that are appropriate for each level and the *types* of activities that are appropriate for supervision at each level. It is essential that the types of supervision be matched to the activities to be supervised at each level. Failure to do this will result in a school psychologist receiving supervision (and evaluation) by a person who is not qualified to engage in that supervision and evaluation. Although we all might like to limit the types of supervision we receive to clinical supervision by qualified practitioners in our own discipline, reality would indicate that school psychologists will receive more supervision by non-school psychologists in the future.

Supervision and Evaluation

The process of supervision is linked to the process of evaluation. Arguably, it is the process of evaluation that has the most negative connotation for school psychologists. More specifically, school psychologists are most concerned about evaluation when the impact is financial or involves job security. School

FIGURE 1. Example of professional activities as a function of level and type of supervision

TYPES		Levels of Supervision		
		Individual	Building	Unit
	Clinical	Counseling skills	Social skills program	Supervision of supervisors
	Administrative	Paperwork	Team-based issues	Outcomes

psychologists are more likely to embrace supervision and evaluation when evaluation is formative and primarily serves to inform the process of supervision to enhance skills or outcomes. However, when the supervision-evaluation process affects salary or job placement, then concerns arise and efforts are initiated to put limits on supervision/evaluation.

The school reform movement increased the level of accountability expected of all professionals working in the public schools. School psychologists are no exception. Increasingly, administrative supervision has included the expectation that school psychologists (or student services teams) will be able to demonstrate the degree to which the services and interventions they provide are effective and have positive impact at the individual, classroom, or building level. School psychologists should be aware of methods of program evaluation that will enable them to demonstrate program effectiveness. At the same time, supervisors must provide the leadership necessary for staff to acquire and implement program evaluation skills. Program evaluation serves four basic functions. First, it provides the opportunity to demonstrate the effectiveness of a particular program or intervention. Second, program evaluation serves to inform program modification, when necessary. Third, program evaluation serves to identify the professional development needs of staff. Finally, program evaluation data serve to promote program development and funding for expansion of staff. However, program evaluation must be fair and equitable to all involved. The process of supervision is complex. Poorly organized evaluation processes will serve only to render supervision functionally useless.

What, then, can be done to ensure that the supervision-evaluation process is fair and equitable? The following guidelines are suggested to ensure fairness and equity:

1. Define the types of supervision and levels of supervision that will be provided to school psychologists.

2. Identify the specific content and activities that will be the subject of the different levels and types of supervision.

3. Develop evaluation measures that are mutually agreed upon both by the supervisor and the school psychologist *for each of the levels and types.*

4. Communicate, prior to the implementation of the supervision and evaluation plan, the proposed use of the evaluation information.

Comprehensive Model of Supervision: An Example

Figure 1 provides examples of professional activities that would be subject either to clinical or administrative supervision at the individual, building, or unit levels. It is possible that each of the "cells" in the figure could be composed of discrete activities (as in Figure 1) or the cells could be composed of different parts of a single activity. As an example, we will examine how the different types of supervision and different levels of supervision might be applied to a case involving the implementation of a building-wide program to reduce bully behavior. In this example, we will assume that there are a number of students who are actively bullying and the building principal wants a program both to address the individual students and prevent building-wide problems in the future. Assume that the program will involve small group work with a number of bullies (e.g., anger control training), the implementation of a building-wide social skills training program, training teachers to implement classroom social skills training, and the implementation of a data tracking system for program evaluation. This is an example in which all levels and types of supervision will be active.

1. *Clinical-individual:* The school psychologist might choose to seek collegial supervision for the implementation of an anger control training group.

2. *Administrative-individual:* The school psychologist will receive supervision from the building principal in order to receive approval for the anger control training group, to coordinate discipline procedures for these students, and to agree on "indicators of success" for these students.

3. *Clinical-building:* The school psychologist might choose to seek supervision from colleagues or the supervisor of psychological services on the development and implementation of the programmatic aspects of the classroom-based social skills program.

4. *Administrative-building:* The school psychologist would receive supervision from the principal or

teacher supervisors on the logistics (communication, scheduling, expectations) of the implementation of the classroom-based social skills training program.

5. *Clinical-unit:* The school psychologist would receive supervision from the supervisor of psychological services on the development of a "training the trainer" model for implementation of this program in other parts of the district or might receive supervision regarding how to supervise the teachers in the building who are implementing the program.

6. *Administrative-unit:* The school psychologist would receive supervision from the building principal regarding the outcomes of the program in the building and in modifying the program based on those outcomes.

School psychologists work in multiple settings each week. It is unrealistic to assume that a single model of supervision could apply to those settings. It is also unrealistic to assume that a single set of qualifications for a supervisor (e.g., same discipline, more experience) are sufficient to provide quality, effective supervision across those settings. The important factor here is to ensure that the *appropriate* type of supervision is available for the *appropriate* setting and activity. It is the outcome of supervision that is important, not who provides that supervision. If the process of supervision results in improved skills, facilitated program implementation, and demonstrated outcomes of services, then the supervision is appropriate and effective. It is the responsibility of the school psychologist, building and district administrators, and district superintendents to recognize that (a) different types of supervision are appropriate and (b) appropriate supervision is available. It is important that school districts and agencies use a rubric such as the one in Figure 1 to define activities that are appropriate for each of the types and levels of supervision, to agree on the content of the rubric, and to communicate and implement the rubric consistently.

By using the rubric in Figure 1, a model of evaluation can be applied to the supervision structure. The content of the evaluation in Figure 2 is taken from the "bully" example from the previous section.

Supervision at the Systems Level

In large school districts or agencies, supervision of psychological services may be consolidated at the systems or centralized level. In a recent survey of supervisors of school psychologists (Hunley et al., 2000) respondents indicated that program maintenance was frequently a major part of their daily responsibilities. Respondents reported that program maintenance typically included program administration and personnel issues. Program development was also reported to be a common responsibility for supervisors. Other job responsibilities that were reported to occur "sometimes" included program evaluation, linkage within and between agencies, conflict resolution, and developing and managing budgets. Finally, the results of the

Figure 2. Evaluation methods/outcomes by types and levels of supervision

		Levels of Supervision		
		Individual	Building	Unit
TYPES	Clinical	• Observation • Student participation	• Review of program • Teacher preparation • Teacher satisfaction	• Review of program • Trainer participation • Numbers trained by trainer
	Administrative	• Student behavior problems	• Principal observations • Principal review of program • Teacher satisfaction	• Discipline problems • Implementation issues • Program modification

study revealed that supervisors "infrequently" engaged in research, personnel grievances, and grant writing. The results of this study support the concept that supervisors spend at least some of their time in professional activities at the systems level.

In the Comprehensive Model of Supervision, there are two primary roles and responsibilities that are undertaken by the supervisor at the systems level. The supervisor is responsible for program maintenance and program planning and organizing. Program maintenance refers to the day-to-day management of school psychological service delivery in terms of personnel, resources, and accountability. Program planning and organizing has a proactive orientation, which emphasizes goal setting, growth, and development.

PROGRAM MAINTENANCE

One basic program maintenance responsibility of supervisors is to manage resources effectively and efficiently with the goal of creating a positive physical environment. Budgeting, data management, and communication technology are important in the promotion of high quality psychological services for children and youth in the schools. The supervisor secures proper office space, equipment, supplies, and personnel in order to reduce wasted time and effort expended by the school psychologist practitioners that could be spent in direct, indirect, or prevention services for children.

Program evaluation and goal attainment monitoring represent another aspect of program maintenance that is critical to the successful delivery of services. This is accomplished through cumulative data gathering that is generated in the process of individual administrative supervision. In addition to the individual evaluation and monitoring of professional skills, the supervisor must consider the efficiency and effectiveness of the unit as a whole. Furthermore, the supervisor is responsible for ensuring that services are delivered according to legal, ethical, and best practice standards. The supervisor acts as a liaison to the school and community in order to enable the school psychological service unit to be responsive to client needs and to provide program evaluation and goal attainment accountability information.

Supervisors of school psychological services spend some daily management time and effort in direct support of their supervisees. They work to motivate practitioners to perform well, and they manage conflict that might impede service delivery. School psychologists are motivated and encouraged by the supervisor who provides emotional support, encourages stress management techniques, and offers rewards for jobs well done. Conflict management occurs through team building, networking, delegating, and specific conflict resolution strategies.

PROGRAM PLANNING AND ORGANIZING

The supervisor of school psychological services actively engages in program and staff growth and development. Proactive programmatic planning and organizing, and staff development begin with shared goal setting, decision making, and problem solving. Effective leaders work diligently to promote the growth and development of effective programs that can be delivered by the school psychological services unit.

Staff development is encouraged through effective hiring and placement decisions, and through ongoing professional development activities. The supervisor is responsible for advocating for funding through the local district as well as for identifying and securing funding from external sources to support sufficient staff to meet the needs of the school district. The recommended ratio of school psychologists to students is 1:1000 (National Association of School Psychologists, 2000). Hiring and placement decisions often are made by a committee; however, the supervisor provides information to the committee to ensure that decisions are appropriate and that there is a good match between the expectations of the applicant, the needs of the school district, and the school psychological services unit. The supervisor is frequently responsible for determining the work setting and job responsibilities for each of the school psychologists. Such decisions must be made based upon the professional and interpersonal skills and interests of the practitioner, as well as the specific requirements of the placement setting. For example, it is generally most beneficial to maintain the school psychologist in a setting over a number of years in order to promote the development of an understanding by that individual of the setting as a system and an effective working relationship as a member of that system.

The supervisor further encourages staff development by offering a variety of ongoing professional development opportunities. In addition to providing direct individual clinical and administrative supervision, the supervisor supports other professional development opportunities that are necessary to achieve the professional goals established by the individual practitioners and by the unit as a whole. As much as possible, the supervisor secures financial support, professional leave, and information about such professional growth opportunities.

Program development occurs when the supervisor facilitates collaborative efforts within the unit and between the unit and other relevant groups. For example, the unit may work toward the implementation of a new program for substance abuse prevention by collaborating with various groups within the school district, state or national organizations that fund grants, and community agencies. In this scenario, the supervisor may serve as the interagency linker, a grant writer, and program implementer.

Leadership

In general, supervisors who adopt the Comprehensive Model of Supervision use the Human Resources approach (Sergiovanni & Starratt, 1998) for supervision. Harvey and Struzziero (2000) recommend this approach and describe supervisors as "key members of the leadership team. They link top administration to supervisees but also link supervisees to top administration, taking an integrative rather than a buffering role" (p. 46). Top administration, while clearly important, represents only one element of the client system. All groups in the client system must be represented, as supervisors work to link them with the school psychological services unit.

The role of the supervisor at the systems level is to demonstrate effective leadership, which unites the school psychological services providers with the clients they serve in pursuit of common goals. This is accomplished by building strong interpersonal relationships (Havelock, 1973), identifying common goals (Harvey & Struzziero, 2000), developing and implementing action plans that are acceptable to all relevant parties, sharing outcome data, and communicating among and between the parties on a regular basis. Goldberg (as cited in Harvey & Struzziero, 2000) suggested that "Leaders do not dominate others, but encourage others to adopt group goals as their own. They also build highly functional teams to achieve these goals. Effective educational leaders are characterized by vision, tenacity, self evaluation and improvement, time commitment, and career dedication" (p. 48).

Three major aspects of the leadership process have been offered by Chemers (1993) in his integrative theory of leadership. Leaders operate by image management, relationship management, and resource utilization. He defines image management as those aspects that affect the perception of the leaders by others. Relationship development encompasses the leader's efforts to establish an exchange that motivates followers' efforts and guides those efforts in productive directions. Resource utilization concerns the ability of the leader to make the most effective use of his or her own energies and the talents, efforts, and resources of subordinates in the accomplishment of organizational objectives.

Although Chemers' (1993) underlying position regarding the three major aspects of leadership has merit for supervisors of school psychological units, it suffers from the traditional view that supervision is directed inward, toward the unit, with little recognition that the same principles apply to the clients in the system that are external to the unit. The Comprehensive Model of Supervision would support a broader perspective in that images, relationships, and resources are managed with the understanding that service providers and clients in the system have an investment in the outcomes of psychological services provision.

Future Directions

Supervisors are in an excellent position to provide leadership for the entire field in the advancement of school psychological services in schools. They can encourage positive changes in the field, and minimize trends that could adversely affect the delivery of school psychological services to children in schools. In the survey by Hunley et al. (2000), supervisors clearly identified two primary needs. First, the study revealed that school psychologists lacked a clear identity as supervisors. The vast majority indicated that they were identified through a variety of different job titles and many reported feeling isolated from others in similar positions. Second, they reported having had little or no training in the supervision of school psychological services, and, as a result, many expressed interest in professional development opportunities that are specific to school psychology supervision.

In response to these issues, an advanced recognition system for supervisors of school psychologists has been proposed for consideration by the National Association of School Psychologists. This system would not represent a required credential for practice but, rather, a means for recognition to identify, to the school psychology profession and to the public, those school psychologists who have met national supervision standards. It would also promote professional identity, increase visibility, and improve accountability for supervisors. Finally, an advanced recognition system encourages the professional growth of supervisors.

SUMMARY

Supervisors of school psychological services are in an advantageous position to provide leadership to the field in the provision of mental health and related educational services for children in the schools. In this chapter, past trends, a new model, and future directions of supervision of school psychological services were discussed. Leadership was emphasized as an effective means for promoting best practices and specific competencies were identified. The chapter reviewed direct and indirect approaches to supervision and recommended a Comprehensive Model of Supervision that incorporates both approaches. Supervision of the individual practitioner and the use of a systems approach provide linkage between the school psychological services unit and the school and community were highlighted. Recognition of the impact that supervisors have on services delivered to children in schools is essential to the field of school psychology. Such a stance requires the support of professional organizations and the educational community.

8 Best Practices in Supervision of School Psychology Staff

Randy Allison
Heartland Area Education Agency 11

OVERVIEW

Supervision of school psychology staff, regardless of the model, is a complex, demanding, and multifaceted task (Conoley & Bahns, 1995; Harvey & Struzziero, 2000). To consider supervision as anything less would be a significant misunderstanding of the supervision role and its potential to affect the quality of services provided by school psychologists. Just as the role of school psychology has evolved, so has the need to consider the role of supervision as evolving. As the demands increase on the practice of school psychology, so do the demands on individuals who provide supervision to assure those individuals who practice are truly developing the required competencies. But supervision needs to be viewed as more than just developing competencies. Supervision should be seen as the responsibility to provide leadership.

Historically, supervision is described in terms of methodologies, the intent of supervisory action, and the professional development of interns. Though the literature on supervisory practices in school psychology is not abundant, there are several sources that address the critical aspects of supervision, as it has been traditionally defined (Knoff, 1986; Zins, Murphy, & Wess, 1989; Conoley & Bahns, 1995; McIntosh and Phelps, 2000; Harvey & Struzziero, 2000). Most recently, McIntosh and Phelps (2000) defined supervision as an interpersonal interaction between two or more individuals for the purpose of sharing knowledge, assessing professional competencies, and providing objective feedback with the ultimate goals of developing new competencies, facilitating effective delivery of psychological services, and maintaining professional competencies. Harvey and Struzziero (2000) described supervision of school psychologists as having the four goals of providing leadership, enhancing the functioning of the supervisees, fostering self-supervision, and protecting clients served by school psychologists.

BASIC CONSIDERATIONS

The purpose of this chapter is to describe pragmatically the considerations and activities required for supervising school psychology staff when an organization is changing its practice to a problem-solving, needs-based, orientation from a traditional, categorical, orientation. The opinions and positions in this chapter could be used with any of the other styles or methodologies of supervision described elsewhere in the literature.

The considerations and activities described in this chapter are derived from the professional literature and a retrospective compilation of supervisory methods employed during the 1990s at Heartland Area Education Agency 11 in Johnston, Iowa. More than 60 school psychologists are employed to serve the 56 school districts that comprise this intermediate service unit. A problem-solving model of addressing student needs has been used in Heartland beginning in 1990. The process of transitioning from a traditional test oriented, categorically focused model to a new system of service delivery provided the impetus for the supervisory strategies that are discussed in the remainder of this chapter.

BEST PRACTICES IN SUPERVISION OF SCHOOL PSYCHOLOGY STAFF DURING CHANGE: SUPERVISORY CONSIDERATIONS FOR INSTITUTIONAL CHANGE

Supervision is a complex, multifaceted task. As such, it is important to identify the critical features requiring attention. Keys to successful supervision for institutional change are presented below. Each of these keys will be addressed in more detail to further illustrate the concept.

Keys to Supervision Through Times of Change

1. Knowledge and skills in leadership
2. Understanding and appreciation of the change process
3. Vision of the future and the subsequent needs of staff
4. Knowledge and skills in the innovation area(s) being changed
5. Skills in evaluation and monitoring
6. Understanding of the impact of educational change
7. Recruitment and maintenance of staff
8. Alignment of critical elements within the system

KNOWLEDGE AND SKILLS IN LEADERSHIP

Professional supervision requires knowledge of leadership and the practice of leadership skills. Tally (1990) notes that leadership is the key to advancing a profession with professional advancement being operationalized as putting into reality the theories and concepts of the continuously changing professional field. Barker (1992) suggests that leaders are people you would follow to a place you would not go by yourself. Covey (1990) proposes that leaders define the direction of the organization rather than simply managing the operations of the organization. According to Patterson (1993), managing is critical to the success of an organization and is performed at all levels within the organization. Managing is a necessary part of what leaders must do. But, managing is not the same as leading (Patterson, 1993). A leader is one who others look to for answers, come to for advice, or seek for support in difficult situations. Strong supervision is about strong leadership. Leaders make accepting challenges productive, experimentation possible, and change more likely. The leadership abilities of the supervisor create the climate for opportunities to become realities.

Grimes and Tilly (1996) suggest leaders are individuals who have a significant influence on others. Leadership does not simply refer to a position of power or designated authority. We can all recall individuals who were leaders but were not people of authority. Likewise, we can recall people who were in positions of authority but did not lead. What makes this difference? Sergiovanni (1992) answers this question in relation to the concept of power. Sergiovanni describes one type of power as that power that emphasizes controlling what others do, when they do it, and how they do it. Alternatively, a more constructive type of power is described as empowering others through shared goals, purposes, and actions. Senge (1994) referred to this as shared vision. Grimes and Tilly (1996) referred to empowering staff when there is a clear message from leadership, a commitment to experimentation and support of staff, and an understanding that the results of efforts will be used to evaluate progress and establish the necessary next steps. Additionally, Patterson (1993) suggests that leadership requires openness to participation, diversity, conflict, reflection, and mistakes.

UNDERSTANDING AND APPRECIATION OF THE CHANGE PROCESS

To effectively lead professional staff a supervisor needs to understand the change process. During the initiation of changing practices, leadership as a supervisor requires disrupting what is currently being practiced in order to gain knowledge and skills in new areas. Fullen and Stiegelbauger (1991) provides insight for supervising in circumstances where change is inevitable. In essence, Fullen suggests regarding uncertainty as common, acknowledging that change will take years to institutionalize, viewing disagreement as expected and valued, and seeing change as a person by person initiative. Given these important considerations, what is a supervisor to do? The answers to this question require careful contemplation.

During change, leaders need to encourage taking risks and experimenting as new information is gained. Just as effective analysis of a problem allows for increased effectiveness of the resulting intervention, effective analysis of the variables in a changing system can enhance the potential for positive and productive results. As staffs learn new and different skills they will make mistakes. Leadership requires tact in positively addressing mistakes and not punishing them. Viewing mistakes as teachable moments for giving better guidance and direction is far more powerful than just pointing out what was wrong. Reinforcing even the smallest efforts of staff when they move in the desired direction is essential. It is also essential not to reinforce undesirable practices, send confusing messages about what is expected, or inadvertently punish positive practice. High frequency reinforcement for doing the expected things is powerful, but so is subtle non-reinforcement. As an example, telling staff that intervention involvement is important but telling them they must adhere to a strict building schedule that inhibits flexibility or availability is counter-productive. If intervention models are to be successfully supported, then staff will need flexibility in scheduling and availability to different teachers and buildings for follow-up.

Effective change takes time. Consequently, making judgments about the impact of new initiatives also takes time. Supervisors should recognize changing practice will have increasing impact over time. Evaluative processes need to be on-going and focused ahead of day-to-day implementation. For example, at Heartland Area Education Agency many innovations that were trained (i.e., progress monitoring, curriculum-based evaluation (Howell & Nolet, 2000), and problem analysis) did not systemically demonstrate themselves consistently for 2–3 years in day-to-day practice. Supervising staff through the adoption of a new approach to practice requires patience. Skills, attitudes, and practice will not change quickly. It is important to assure staff has new skills before they can be expected to attempt new practices. Staff should be expected to give up a current practice only after they have learned new replacement skills. For example, do not require staff to use new skills or technology such as curriculum-based assessments until they are trained on why and how to use them. It is not productive to tell staff what they can no longer do without providing alternative skills. Leaving staff in the dilemma of not being expected to do what they were most accustomed to and not having them trained in a replacement skill will cause agitation and create helplessness in staff. There will be a tendency to view old practices as simpler, easier, more comfortable, and possibly more desirable.

Disagreement is inevitable but fundamental to change. Keep in mind there are many factors that contribute to success or failure. There are no absolutes or guarantees. Supervision should not to be misunderstood for a popularity contest. Address disagreement by allowing input and open communication. If staff is having a difficult time accepting the need for change, then actively engage them on issues of concern. By actively engaging staff in the difficult issues they take more interest in, invest more energy, and ultimately come away with more knowledge and understanding than if left out of the discussions. As staff acquires new knowledge, skills, and roles there may be general discomfort until they become as skilled in the use of the new skills as they were in the use of previous skills being replaced.

It is imperative that supervisors accept staff where they are, continue to show them the intended outcome for practice, and provide them with ongoing support to reach their target. Staff will learn and accept new skills in different ways and at different times. Assuring that new skills are connected both literally and conceptually is important for meaningful change. One-trial learning is not likely. Multiple opportunities to learn, time to practice, opportunity for feedback, and eventual refinement need to be taken into consideration and planned for (National Partnership for Excellence and Accountability in Teaching, 2000).

If staff will be expected to learn and practice new skills, then they will not only need training but new materials with which to practice the new skills they have learned. Providing materials for staff to use is far more effective than expecting staff will create and use them on their own. After all, staff time is valuable and limited. Given a choice between using existing materials or creating new ones, most staff will resort to what is easy to get their hands on. This means that staff may use the very practices we would want them to move away from if the materials for intended use are not more readily available than those typically used. For example, if curriculum-based measures are to be used in lieu of nationally standardized norm-referenced assessments, the access to the probe materials needs to be as easy, if not easier, than the test kit. If not, then staff will continue to use the test kit out of necessity of time and efficiency. This inadvertent reinforcement of old or past practice can substantially slow and limit use and adoption of new methodologies.

VISION OF THE FUTURE AND THE SUBSEQUENT NEEDS OF STAFF

Supervision requires knowledge of current staff needs and trends in the field. Supervision should not just be about helping staff do what they have always done. Leadership requires looking into the future for better answers for today's concerns and facilitating those solutions. This makes supervision of staff a difficult task given the vast range of knowledge and skill required for competent practice. This necessitates focus. It is important we focus on the important outcomes that must be taught and mastered. Supervisors cannot be deterred from their focus by activities that seem interesting but are not related to desired outcomes. Without an outcome orientation, it becomes too easy for staff to fall into patterns of comfortable practice and continue to do what they have always done. Supervisors must have a clear, focused, and well-articulated plan of action from which to lead.

Often changing practice is viewed with an "installation mentality." In other words, we approach systemic change like we approach purchasing a new piece of software. We assume we will get the disk, possibly read the manual, install the program, and we are up and running. This is not possible for the purposes of getting real change to occur. In fact, this approach can confuse issues and make matters worse. If we do a poor job of planning or implementing, then we may, in effect, inoculate the system against future change efforts. For example, training staff to use curriculum-based measures for assessment of academic skill attainment yet continuing to value grade equivalent scores from achievement batteries sends a conflicting message. While experimentation and risk-taking are necessary, short-sighted planning, failure to develop understanding, and poor implementation will have the unintended effect of introducing resistance to doing anything differently. Staff will come to believe that "this too shall pass." A better approach is to start small, work smart, and look for ways to find success on measurable outcomes. Knoff (1995) clearly delineated the necessary process of institutionalization of new innovations. The requirements are (a) establishing improvement as the priority; (b) having personnel guiding services by contributing to new policies; (c) staff receiving ongoing support for innovative practices from leadership; (d) staff develop essential skills, knowledge, and attitudes (staff development); and (e) there is alignment between the vision for change and agency procedures, goals, and roles.

KNOWLEDGE AND SKILLS IN THE INNOVATION AREA(S) BEING CHANGED

Supervisors must completely understand the philosophical basis for the programs and services being implemented. For example, if the organization provides problem-solving, needs-based assessments with data-based interventions, then the supervisor needs to understand the fundamental principles of a problem-solving, needs-based model. Implicitly, the supervisor must be able to define the critical components and the expected outcomes of the innovation area being changed. This may sound rhetorical but it is easy to tell staff what they need to be doing without staff truly understanding what to do or why. Proof of true understanding lies in the supervisor's ability to help staff explain why they are doing what they do. Teaching skills without connections to the critical components, without an appropriate context, and without the fundamental thinking attached will result in only a false appearance that practice is improved. Explicit connections need to be made, demonstrated, and reinforced. It is an oversight to provide training on a new concept or skill and assume that staff will know the intended connections to their current practice or philosophical understanding. By providing clear and meaningful direction, staff is able to see the connections for themselves, they are able to explain their actions to others, and they are able to make decisions in a clear, concise, and reliable fashion. If the answer to questions about why new practices are in place is "because that's just what we do now," or "because my supervisor told me to," then we will not go far with the change process or our long-term plan.

Leaders must to be able to offer broader perspectives on innovations and be able to link different innovations together. In today's educational system it is increasingly important to establish meaningful connections and build on existing programs as resources, time, and opportunities are limited. Without careful consideration, new ideas and practices will be viewed as an "add on" and not be meaningfully embedded within the context of existing practices.

SKILLS IN EVALUATION AND MONITORING

Knowing where staff skills are, where staff skills need to be, and how far staff needs to go to reach desired performance targets is at the crux of supervision. This allows supervisors to set goals, implement plans for change, monitor progress, and make decisions about progress. During times of change, supervisory monitoring of staff is critically important. Staff monitoring is critical to gauge implementation integrity and skill development. Monitoring also informs the supervisor of next steps for staff development. Monitoring points out the need to revisit areas already trained or to provide training in new areas that would be logical next steps in the staff development plan. The supervisor needs to plan staff development aligned with the vision and in relation to current skills. Once the direction is set and the level of current practice is determined, a clear course of staff development opportunities can be crafted to provide the needed skills. Individual and group monitoring allows the supervisor to carefully consider staff progress toward individual and group goals. This information is also helpful to staff in pointing out areas of continued improvement and personal growth. An additional requirement of supervision is to anticipate the next needs of staff to move them to the next level. By organizing staff development to stay in front of the learning curve you are able to guide staff to the next level you intend for them to go.

A frequent question that is asked is, *What do we need to train to promote a problem–solving system?* The answer to the question is another question: *What are the critical components of the problem–solving' process and why?* Too often the problem-solving process is erroneously seen as a simplistic model that does not require the attainment of many, if any, new skills. Problem solving, as a system of service delivery, requires numerous critical components to be in place for successful implementation. At a minimum, methods of operationally defining problems, functional assessment, analyzing problems for intervention design, monitoring student progress, and evaluating data to make reliable and valid decisions are needed. In addition to these essential components is the requirement that staff be skilled in consultation and collaborative teaming. Ikeda, Tilly, Stumme, Volmer, and Allison (1996) described staff development needs in two ways. First, potential areas for staff development should be critically reviewed so that limited resources are not used on training that is not effective for or relevant to problem solving. Second, staff development should be linked to the philosophy inherent in the foundation principles of a problem solving, needs-based model. For example, skills will be required of staff such that problems are specifically and accurately identified and analyzed, interventions are put in place based on the identified relevant features of the problem, interventions are monitored frequently, and intervention results are evaluated to make decisions on effectiveness. Training toward the big picture of system implementation is a must.

UNDERSTANDING OF THE IMPACT OF EDUCATIONAL CHANGE

The practice of school psychology does not occur in a vacuum. Schools are an integral part of many other complex and inter-related systems. As a plan for organizational change is developed it is critical to evaluate the impact of changes in one system on changes in other systems. It is also important to evaluate the unintended effects of organization change efforts. Unintended effects could be either positive or negative. Supervisors, as leaders during institutional change, should assume a role of introducing initiatives to important constituents such as school personnel, parents, and outside agencies in order to minimize unexpected difficulty while taking unnecessary burden off of staff.

District personnel need to understand proposed changes and why they are being considered. In addition, district personnel need to know what will be new and what services will no longer exist. Without this knowledge we invite administrators and teachers to pay too little attention to what staff is doing differently and become focused on what they are no longer receiving. For example, if teachers are focused only on whether or not a student receives an IQ score, then they may not attend to the specific strengths and weaknesses that are derived from a more direct assessment of student skills. District personnel become very accustomed to patterns of services. Without proper information school personnel may not be able to immediately see the intended value of providing services differently.

An aspect of leadership that is often not fully utilized is the provision of information to districts and district staff. Often, school psychologists are instructed on new skills and practice and then expected to introduce these new skills to the district and building staff. This sets up the difficult circumstance of staff's being the bearer of information regarding new or different practices. Additionally, staff is expected to be the implementers of changes. This can inadvertently reduce the acceptability of staff because of the emotional influence and stress related to change. For example, if general education interventions are required, then schools may be concerned with the analysis and monitoring requirements. It is easier for the supervisor to explain the needed requirements so that staff being asked to implement the change are not inadvertently accused of making the requirements more difficult or challenging. This is particularly true when staff is just learning skills themselves and may need support in the assimilation of new practice. As a supervisor, it is possible to introduce issues, changes, and underlying philosophical differences and not have them attributed to staff responsible for implementation.

Parents need to be informed and apprised of changes with clear rationale and explanation. Otherwise, they too may be expecting specific practices based on previous experiences. When parents' expectations are not met they may question and resist without a proper explanation of what has changed and why. Again, supervisors can play a crucial role in parental awareness.

Finally, outside agencies and other allied institutions have come to rely on schools to provide assessment information, often in a very specific way. When a system changes to a problem-solving, needs-based model and new practices are employed, the usual set of information typically found in student files may no longer be available. Without proper groundwork, staff will be inundated with requests to provide the usual sets of information and receive complaints about what is no longer available. For example, waiver services, departments of human services, adult services, or physicians may be accustomed to simply asking for and receiving specific test results. In a needs-based model many of the assessments traditionally performed in schools will no longer be necessary for educational programming. It is important that as staff is trying new methods, learning new skills, and acquiring the critical components of a new system that they are not overly involved in the negative fallout of system level realignment. It is the role of the supervisor to negotiate and navigate these difficult system level issues to divert the attention and emotionality from professional staff.

RECRUITMENT AND MAINTENANCE OF STAFF

A critical responsibility in effective supervision is recruitment. As staff openings occur it is imperative that new staff is carefully selected to meet the current and future needs of the system. It is counterproductive to attempt to move to a new approach to business and not spend significant effort to find the very best individuals who can support the system when opportunity arises. Too often educational agencies simply "fill" positions, go to the local university, or rely on other passive means of filling vacancies. An active, specific, and clearly defined approach to finding, recruiting, hiring, and maintaining the very best trained and philosophically aligned individuals available is fundamental to responsible leadership. When hiring staff from universities or colleges, it is important to recognize not all programs are equal despite being National Association of School Psychologists or American Psychological Association accredited. University programs do not produce individuals with the same skills or philosophical orientation. Hiring individuals who are not philosophically aligned and who do not have strong interpersonal skills is detrimental to institutional change. As a leader it is imperative to know what skills practitioners need and which universities are training students to meet those requirements. This increases the likelihood that students come with the needed attributes and attitudes.

ALIGNMENT OF CRITICAL ELEMENTS WITHIN THE SYSTEM

Supervisors should consider alignment on two levels. One level is conceptual. Are the concepts we are supporting in line with and compatible with each other? Another level is procedural. Are we applying procedures that are in line with each other and in line with the conceptual model? Without these areas of alignment the practices within the system will vary from the philosophy underlying the system. What follows are examples of alignment used at Heartland Area Education Agency to ensure conceptual and procedural matching. Actual examples of how these alignment tools might look are also provided to give a visual representation of the concepts discussed.

Activities and Outcomes. Aligning the problem-solving system with supporting infrastructure is a critical task to build support from within and to reduce confusing practices that detract from the focus of the system change. Alignment starts with a serious look at the critical activities that staff will be expected to be engaged in and what the expected outcomes of those activities will be. This is the point where roles are defined, resources are allocated, and staff actions are prioritized. Secondarily, these activities and outcomes start the framing of staff development needs because staff will be expected to be able to competently perform the activities in order to achieve the expected outcomes. Figure 1 is an example of part of an activity and outcome document. Note the focus on activities and outcomes aligned to a problem-solving orientation.

Figure 1. School psychology activities and outcomes

Activities:	*Outcomes:*
Consultation School psychologists use various consultation models to consult with educators, parents, students, and other professionals or agencies to (a) accurately problem solve and design effective interventions; (b) improve educator, parent, and agency understanding and effective implementation of designed interventions; (c) promote and advance mental health issues of families, children, and youth; and (d) advance the transformation of the educational system to meet the needs of a broadening diversity of children in need.	Evaluation and assessment will be guided by identified problems resulting in individualized, need specific, assessments unique to the student, family, or system. Those involved with interventions will have the knowledge and understanding necessary to carry them out and apply them to other similar conditions. Those working with families, children, and youth will be proactive when addressing the complex needs related to sound mental health for those with whom they work and will be better able to plan and problem solve solutions in a preventative manner. As system-wide changes in education unfold, children, families, and schools will benefit from the most current, research based, adaptations possible.
Assessment School psychologists provide functional assessments that are (a) relevant to the presenting identified problem and student characteristics; (b) efficient and incorporate relevant biological, social, cognitive, and developmental domains; (c) relevant within the context of home and school; and (d) intervention oriented and technically adequate.	Assessment will lead directly to answers to specific questions about the various factors influencing the identified problem. Designed interventions are focused and data based resulting in increased rates of successful change in student performance. Finally, psychometric and best practice considerations are optimized.
Interventions School psychologists assist those with whom they work by helping develop individualized or system-level interventions that improve or resolve the identified problems or concerns by (a) utilizing a problem-solving approach; (b) incorporating applied behavioral analysis to the presenting conditions or the problem; (c) focusing on the appropriate source of the issue be it student, family, or educational system; and (d) collecting data to reflect progress toward the goal and adjusting the intervention as the data indicate.	This ensures the appropriateness of intervention strategies designed for the recipient(s) of the intervention. Interventions can be written on an identified problem that is well defined, incorporates problem analysis, and includes details of the actual intervention (such as what will be done, when it will be done, how it will be done, and by whom) leading to increased integrity in implementation. Students, families, or school systems will demonstrate measurable improvement in the problem area identified because of careful design and implementation of more effective interventions.

Job Descriptions. After activities and outcomes for staff are clearly defined and articulated it is important to include them in the professional job description. A staff members' job description should reflect the activities and outcomes the staff will be expected to perform. This is the first step in productive and responsible recruitment of new staff for the desired skills and orientation for the position. The job description is also a guiding document for staff evaluation. Without a clear job description and role definition there is increased potential for staff to simply continue doing what they always have and for new staff to be hired with a philosophy, orientation, and training that will not promote, enhance, or support the organizations' vision. Figure 2 is part of a job description for school psychology. Note the match in the job description to the previous activities and outcomes.

Professional Staff Evaluation. It was mentioned previously that staff needs a clear set of expectations and a well-articulated plan for performance. The professional staff evaluation plan is the component in the system of supervision that links the activities and outcomes, the job description, and staff development to actual day to day performance. Staff needs to know that there are clear expectations for performance and that they will be professionally evaluated based on their acquisition and demonstration of required system components.

Professional staff evaluation takes on several very important functions during change initiatives. First, it provides a method of performance feedback and monitoring of skills for staff. It shows that specific elements of practice are clearly important and must be accomplished for satisfactory job status. As importantly, it allows staff to celebrate their successful

Figure 2. School psychology job description

Position title: School Psychologist

Primary objective of position:

Provide school psychological services that assist parents and professionals in meeting the educational and mental health needs of children and youth.

Major area of accountability:

1. Develop individualized or system level interventions that improve or resolve the identified problems or concerns.
2. Provide support, instruction, technical assistance, and ongoing monitoring of progress toward measurable, identified goals.
3. Provide functional assessments relevant to the presenting problem and student characteristics and are intervention oriented.
4. Effectively consult and collaborate with educators, parents, students, and other professionals or agencies to improve client services.
5. Provide individual and group counseling to students and their parents.
6. Participate in interdisciplinary staffings to determine the eligibility, appropriate planning, and re-evaluation for students who require special education programs and services.
7. Manage time, organize necessary materials, and communicate with AEA and LEA staff to effectively manage cases in assigned areas.
8. Involvement in research, interpretation of research, and implementing research findings from single subject and group designs.
9. Provide staff development through membership in professional organizations, inservices, consulting, and research.
10. Engage in public awareness activities that assist consumers in understanding services and the anticipated outcomes of these services.
11. Advocate for the civil rights of students.
12. Assist the supervisor of psychological services as directed in the supervision of interns and/or practicum students or personnel assigned by the director.

Figure 3. Professional staff evaluation

Problem solving	C	NI	U

- Demonstrates understanding of conceptual underpinnings and rationale for Heartland's problem-solving approach
- Demonstrates understanding of the function/purpose of an intervention within the educational process at all levels of the problem-solving approach
- Uses resources effectively to plan and implement interventions
- Demonstrates understanding of how to integrate the problem-solving approach into current existing systems (home, community, and school)

Assessment/intervention	C	NI	U

- Clearly identifies problems and determines why they are happening
- Develops intervention plans that clearly address the concern
- Implements or supports implementation of interventions with integrity
- Evaluates the effectiveness of interventions based on analysis of data
- Conducts assessments for the purpose of planning programs and/or considering entitlement for special education that answer both the question of whether or not an individual has an educational disability or not *and* the question of whether or not the student has instructional needs that require special education
- Uses all the components of effective intervention planning to develop IEP and Individual Family Service Plans that address the needs of students

Consultation	C	NI	U

- Identifies specialized expertise among team members
- Collaborates effectively with all teams, outside agencies, families, and children
- Demonstrates the ability to explain intervention: planning through the problem-solving approach to general education, family and other agencies
- Demonstrates awareness of the structure and hierarchy (system) of LEAs and communities in general as well as their assigned LEAs and communities in particular
- Demonstrates awareness of the LEA curriculum and its goals, standards, and benchmarks as it applies to their assigned job description/function, as well as the interaction of curriculum standards and special education instruction/support
- Demonstrates awareness of the Iowa School Improvement process including district-wide assessment
- Uses an effective consultation model(s)
- Communicates effectively
- Models, guides, and assists LEA staff at all levels of the problem solving process

Note: Rating scale definitions: C, competent: Consistently meets the requirements of the assignment; NI, needs improvement: Growth needed to meet the requirements of the assignment; U, unsatisfactory: Does not meet the requirements of the assignment.

demonstration of skills and be reinforced for their accomplishments. In addition, reviewing staff performance on professional evaluations allows the supervisor to holistically evaluate the staffs' attainment and demonstration of skills. The input from this review of what is going well and what is not is critical in the structuring of a staff development plan that is tailored to the individual and group needs of the school psychology staff. Figure 3 is a portion of the Professional Staff Evaluation form used for school psychology. Note the alignment to Activities and Outcomes and the job description for school psychology.

Alignment of Accountability Paperwork. Paperwork is an ever-present part of the school psychologists' job. Paperwork frequently serves an accountability function. It is important that paperwork requirements for the job be changed to match service delivery expectations. This matching of paperwork serves to guide thinking and practice, assures critical components of the system are completely considered, and that necessary events or activities are captured for accountability or justification at different points in the decision-making process. Since paperwork is a required component of any system it is important that we use the paperwork to our advantage in guiding and improving practice.

Forms direct practices and procedural requirement. Forms are therefore developed to capture the critical and necessary aspects of the system. Staff is then trained to complete the paperwork directly. In this approach the content and the format match in a one-to-one fashion. This practice assures that completion of the paperwork complies with the expectation of the system. This process trains the thinking that is required to navigate the system. Figure 4 is an example of part of an intervention plan designed to provide guidance in this way. This format is most useful in guiding the practice and learning during acquisition of new skills. Note the detail in the directions to guide thinking and completion of the form in a way consistent with the underlying expectations of a problem solving system.

Program Evaluation. An important aspect of any change process is program evaluation. Program evaluation must be carefully designed to answer the specific questions important to the system at specific points in time. The evaluation process must be sensitive to change and dynamic in nature in order to continually address the important aspects of system change being considered. Historically, program evaluation is predominantly of a compliance nature. Emphasis is placed on the presence or absence of required information based on review. However, the required data typically has little or no relation to the quality of programs and services being provided. Additionally, the compliance orientation often does not address what are considered critical elements of changing systems in order to provide feedback on how well we implement the system as it was intended.

Comprehensive Service Review (CSR) is used at Heartland in an effort to substantively evaluate the level of adherence of staff to the established practice expectations. This process began with a comprehensive look at system expectations. By delineating the critical elements supervisory staff was able to systematically link the critical components of the new process together in a step-by-step fashion. Once the critical elements were defined by their required sub-parts, standards for acceptable performance were delineated in order to establish a checklist of expected components based on requirements of the adopted system. Actual cases could then be systematically evaluated using the CSR document to establish the level of adherence to the standards of prescribed performance.

The use of the CSR has multiple purposes. Staff is able to see the whole process incorporated within the system in a very linear and pragmatic format. This helps staff see a bigger picture of the system requirements and the linkages throughout the process. From a supervisory perspective it allows for monitoring staff on an individual and group basis with regard to the presence and absence of critical features within the system. This presence and absence of critical features is then linked directly to evaluative issues and staff development needs. Figure 5 is an example of part of the CSR form used for program evaluation. Note the relationship of the CSR form to the initial parts of the intervention plan shown previously.

Innovation Configurations/Rubrics. The use of CSR helps in looking at the presence and absence of critical parts of a process and the linkages between the critical components of the model. The presumption is that the more critical elements that are in place the higher the likelihood of success on an individual student basis. From a supervisory perspective, what the comprehensive service review does not do is look qualitatively at the parts of the system that were present. It is important that evaluation of systems take on both the quantitative (presence or absence) and qualitative (how good or bad) features. These features are independently important but highly connected. For example, without the presence of a particular component of the system it is impossible to judge the component quality. At the same time, the presence of a component does not speak to the accuracy, alignment, quality, or justification of the component with other aspects of the system. For example, if a goal is not present in an intervention plan it is impossible to evaluate the goals' quality in relationship to other aspects of the intervention plan. However, the mere presence of a goal may appear to be positive when, in fact, the goal that

Figure 4. Functional paperwork accountability

Intervention plan

Name:______________________ DOB:__________ Date:__________

Problem statement: Behavioral description of the problem; based on problem analysis

What is the target behavior: should be specific, observable, alterable, measurable and focused within educational setting	
What about the behavior is problematic: should address frequency, latency, intensity, fluency, or accuracy	
What is the level expected for the behavior: based on a specific standard of acceptance	
What standard was utilized: consider peer comparison, curriculum, teacher, policy, etc.	
Level of performance before intervention: baseline or pre-treatment performance	
Discrepancy between expected and actual: this defines the size of the problem now	

Goal: Must be measurable and observable; states direction and extent of target behavior change

Conditions: when and how the student will perform the behavior	
Behavior: what the student will do	
Criterion: the acceptable level of performance	
Time-frame: length of time anticipated for the student to reach the goal level

CASE REVIEW PROTOCOL

DIRECTIONS: Indicate by checking "Yes" if the component is present and meets the identified standard. Indicate by checking "No" if not present.

Access	Standard	Yes	No
An **Intervention summary** form was present	Screenings were conducted prior to the follow-up date.		
Demographic information	All complete		
Problem analysis summarized (Check those components present. Check yes if all components are present. Check **no** if any is missing.)	___Target behavior ___Assessment questions ___Convergent data collected		
An **Intervention plan** was present	Variety of different forms		
Problem statement (behavioral definition)	Defines difference between expected and actual behavior using objective measurable terms		
Goal (Check those components present. Check yes if all components are present. Check **no** if any is missing.)	___Written ___Measurable ___Related to behavioral definition ___Includes conditions ___Behavior ___Criterion		
Parental participation	Summarized		
Initial level of performance	Baseline data on the target behavior This is a number.		
Procedures/arrangements **Person(s) responsible** (Check those components present. Check yes if all components are present. Check **no** if any is missing.)	___Method of intervention or strategies ___Where (location) procedures will be used ___When (time of day or during what period of day)procedures will be used ___Time (length of time) for intervention ___Frequency (how often, weekly, daily etc.) ___Materials used ___Persons responsible are listed.		
Measurement strategy (Check those components present. Check yes if all components are present. Check **no** if any is missing.)	___Who will collect data ___Data collection methods ___Under what conditions ___Schedule for data collection.		
Decision making plan (Check those components present. Check yes if all components are present. Check **no** if any is missing.)	___Data are graphed or charted ___Number of data points or length of time before data analysis. ___Decision rule		
Follow up date	Recorded		
Level of performance after intervention	Post-intervention data on the target behavior. This is a number.		
Summary of outcome data	Written summary of outcomes of intervention. Includes interpretation of data

is present is unrelated to the defined targeted behavior and there are no evaluation procedures in place that will allow the goal to be accurately or meaningfully measured. Rubrics or innovation configurations (Hord, Rutherford, Huling-Austin, & Hall, 1987) are extremely helpful in the establishment and supervision of quality indicators in system reform. Figure 6 is an example of an innovation configuration used to evaluate Individual Education Plan (IEP) development. This rubric allows for the qualitative evaluation of an IEP both at a specific point in time and also across time for monitoring purposes.

Figure 6. **Innovation configuration for IEP development**

IEP RUBRIC

Indicator	Not Present 0	Partial 1	Complete 2
Student and family long range expectations	No statement is included.		A statement is included.
PLEP: Content for instructional planning	No reference to either general education curriculum or student instructional needs.	Reference to general education curriculum *or* student needs is included in the PLEP statements.	The PLEP statements include student's accomplishments in general education curriculum or participation in appropriate activities *and* identifies needs of the student.
PLEP: Content needed for decision making	Current levels of performance are not established.	Current levels of performance are established. Current discrepancy *or* current level of independence is identified.	Current levels of performance are established. Current discrepancy *and* level of independence or prediction of independence are included in PLEP.
Baseline	No baseline documented.	Vague description of students current behavior or academics.	Specific baseline clearly representing target behavior expressed in quantitative manner.
Behavior in goal	Behavior in goal is not same as that identified in baseline.	Behavior in the goal is same as that identified in baseline, but is nonspecific and not measurable.	Behavior is stated in specific measurable terms and is the same as that identified in baseline.
Goal components	More that one component of goal missing (time frame, conditions, behavior, and criterion).	Goals contain all but one component (time frame, conditions, behavior, and criterion).	Goal contains time frame, conditions, behavior, and criterion.
Evaluation procedures	Not specified.	A schedule for evaluation progress is identified. Progress is monitored less frequently than once per week.	Evaluation procedures are planned to be frequent and repeatable. Progress is monitored at least once per week.

SUMMARY

Supervision is a complex and demanding array of responsibilities and opportunities. Leadership, as a supervisory charge, is essential for meeting the daily and long-term demands of supervisors. If a central theme of supervision is building and supporting the competencies of school psychology staff, then it requires supervisors to be attuned to immediate and long-term needs of staff. A systemic focus is important to recognize the impact of change and unintended effects. Staff development and on-going training and support of staff is a core necessity of building and maintaining staff performance once strong staff are recruited. Finally, aligning the infrastructure to support staff and system priorities will help train, promote, and strengthen the institutionalization of changes.

ANNOTATED BIBLIOGRAPHY

Grimes, J., & Tilly, D. (1996). Policy and process: Means to lasting educational change. *School Psychology Review, 25*(4), 465–476.

This article provides an excellent overview of the systemic change process in Iowa. It provides information on the foundational considerations and key concepts for consideration. This is a must article for those seeking information on critical components and characteristics of an institutional change process from a state level perspective.

Ikeda, M., Tilly, D., Stumme, J., Volmer, L., & Allison, R. (1996). Agency-wide implementation of problem solving consultation: Foundations, current implementation, and future directions. *School Psychology Quarterly, 11*(3), 228–243.

This article provides insight on agency-wide implementation of a problem-solving, needs-based approach to providing student services. Critical components of the problem solving consultation, as practiced by Heartland Area Education Agency 11, are delineated and described. Case examples are also included.

McIntosh, D., & Phelps, L. (2000). Supervision in school psychology: Where will the future take us? *Psychology in the Schools, 37*(1), 33–38.

This recent article provides a concise overview of issues in supervision. Included in the discussion are definitions of supervision, differing types of supervision, and a view of the research in supervision issues. This article concludes with a discussion of the future needs and considerations in the area of school psychology supervision.

Sergiovanni, T. J. (1992). *Moral leadership: Getting to the heart of school improvement.* San Francisco: Jossey-Bass.

This book provides a view of leadership premised on moral leadership and empowerment. Discussion and examples are provided that illustrate the concepts of leadership based on empowerment as opposed to leadership based on power or cohesion. This is a good book for expanding current thinking on how leadership might be envisioned.

Reschly, D., & Ysseldyke, J. (1995). School psychology paradigm shift. In A. Thomas & J. Grimes (Eds.), *Best practices in school psychology III.* Washington, DC: National Association of School Psychologists.

This article chronicles the highlights of historical school psychology practice and the underlying premises on which services were defined and provided. Problems with current practice are delineated and discussed providing a rationale for the introduction of a different service delivery system based on advances in assessment and intervention practices. A problem-solving process is described as an alternative delivery system. Major considerations and concerns are posed and briefly discussed.

Best Practices in the Supervision of Interns

Jane Close Conoley and Jeremy R. Sullivan
Texas A&M University

OVERVIEW

Supervision is "an interpersonal interaction between two or more individuals for the purpose of sharing knowledge, assessing professional competencies, and providing objective feedback with the terminal goals of developing new competencies, facilitating effective delivery of psychological services, and maintaining professional competencies" (McIntosh & Phelps, 2000, pp. 33–34). Effective supervision of school psychology interns can accomplish several goals. The most important may be developing autonomous skills in direct services such as assessment, psychotherapy, and consultation; learning to translate knowledge into informed, competent practice; learning to apply the most recent ethical guidelines to professional practice; and receiving opportunities to share personal and professional experiences with others on a regular basis (Crespi & Lopez, 1998). Considering these objectives indicates the importance of the supervisor's role in the professional training of school psychologists.

Supervision can be conducted in either an individual or group format, both of which are widely practiced. Advantages of group supervision include peer feedback and support, and exposure to a wider variety of cases, assessment techniques, and diagnostic and treatment issues (Riva & Cornish, 1995). Frequent topics discussed in supervision include ethical and legal issues, advanced clinical skills, assessment and evaluation, diagnosis, theories of psychotherapy, crisis intervention, and administrative issues. Common methods of assessing clinical skills include the use of audiotapes, videotapes, and role plays, in addition to evaluating the accuracy and sophistication of case conceptualizations (e.g., determining proximal and distal factors contributing to clients' issues, considering different levels and methods of intervention, and considering clients' strengths and weaknesses and ways of capitalizing on strengths and improving upon areas of weakness).

Both the American Psychological Association (American Psychological Association, 1981, 1992) and the National Association of School Psychologists (National Association of School Psychologists, 1994, 1997) regard supervision as essential to the professional development and practice of school psychologists and, therefore, regulate the provision of supervision. There is, however, a relative paucity of published literature and empirical research devoted to this area within the field of school psychology, especially when compared to the amount of literature related to supervision published in the fields of clinical and counseling psychology (McIntosh & Phelps, 2000). In addition, most supervisors report limited academic training in supervision and limited access to peer supervision (Robiner, Saltzman, Hoberman, & Schirvar, 1997; Zins, Murphy, & Wess, 1989). The recently published *Effective Supervision in School Psychology* (Harvey & Struzziero, 2000) represents an attempt to consolidate, and draw practical implications from, the literature regarding school psychology supervision. This volume will likely become a popular and important contribution to the field.

An important first step in exploring the supervisory process is for supervisors to attend to and review their own skills, knowledge, and vision for the supervisory relationship. Part of this self-assessment deals with developing a theoretical model to guide supervisory behavior; another deals with constructing standards of behavior between supervisor and supervisee; and, finally, part has to do with creating a plan to engage the intern in informed and ethical decision making in the complex problems facing school psychologists in the new millennium.

The present chapter will consider the needs of the supervisor, the intern, and the client from a number of perspectives. Supervision is carried out with overlapping responsibilities to the intern, the training site, the intern's academic program, and the client. A first step for supervisors is to identify which existing supervisory model is closest to their own theoretical orientation, and to then begin a process of exploration and study.

MODELS OF SUPERVISION: BASIC CONSIDERATIONS

There are several models of supervision based on various theoretical orientations within developmental and clinical psychology, including psychodynamic, client-centered, behavioral, and developmental. Brief comments on each of these models follow. It must be noted that this list is not exhaustive; other models exist (e.g., the case study or case analysis approach).

Psychodynamic Supervision

The primary focus of psychodynamic supervision is on supervisees learning to use themselves effectively in helping relationships. This is accomplished primarily by concentrating on the dynamics of the supervisory relationship in order to monitor constructive or destructive ways of relating to or reacting to others. It is assumed that understanding the relationship dynamics of the supervisor and supervisee will generalize to understanding the dynamics between supervisees and their clients.

Supervisors must build a working alliance with their supervisees. This alliance should be based on a willingness to work together to improve the effectiveness of the intern's clinical skills. Proponents of this model suggest that unresolved personal issues of supervisees (and supervisors) are major impediments to development and growth (Thorenson, Miller, & Krauskopf, 1989). There is little research to support the psychodynamic model. The danger of creating psychotherapeutic rather than supervisory interactions between supervisor and intern has been suggested (Doehrman, 1976) as a key concern with this model.

Client-Centered Supervision

Growing from Rogers' (1958) seminal work in humanistic psychology, client-centered supervision seeks to establish conditions between supervisor and intern that mirror the conditions that are necessary for effective psychotherapy. The therapeutic conditions of psychological contact, congruence, unconditional positive regard, empathy, and warmth are the conditions both necessary and sufficient to foster enhanced self-exploration. Interns must be taught how to create and communicate each of these conditions in their relationships with clients. From this perspective the intern's own professional development in this regard depends on the supervisor's skills in creating and communicating these therapeutic conditions.

Videotapes or audiotapes, modeling, role-plays, and live demonstrations are often components of client-centered supervision. Personal therapy is seen as a very important way of increasing interns' expertise in interpersonal relationships. The demand that supervisors model and implement the same interpersonal and relational conditions that are desired in the interns' therapeutic endeavors has some intuitive appeal. Research indicates, however, that supervisors must teach specific techniques and skills as well as facilitate a supportive environment in order to increase supervisees' effectiveness (Forsyth & Ivey, 1980).

Behavioral Supervision

With the behavioral model, the judgment of proficient performance is based on learned skills. Supervisors must teach appropriate behaviors and extinguish inappropriate ones. Each of the intern's jobs or professional activities can be broken into identifiable tasks with associated skills. The supervisor should use the same behavioral principles with the intern as are used in counseling or therapy situations (Delaney, 1972).

Mutual assessment of skill deficits and strengths are followed by a shared commitment as to the steps to be taken to meet measurable goals. Frequent feedback is provided regarding current progress toward goal attainment. Supervision is conducted through an individualized contract of specific behavioral goals and identification of the means for attaining these goals. The major steps of behavioral supervision are as follows: (a) establish a relationship between supervisor and intern, (b) assess current level of skills, (c) set goals for supervision, (d) generate and implement strategies to accomplish supervision goals, and (e) evaluate the effectiveness of strategies and generalization of learning.

The failure to provide feedback and provide for remedial activities is often the basis for ethical complaints filed by supervisees (Freeman, 1985; Keith-Spiegel & Koocher, 1985). A strength of the behavioral approach is the demand for clear communication and careful monitoring of skill development. A weakness may be a lack of oversight of the intern's personal dynamics that can affect therapeutic effectiveness.

Developmental Supervision

According to this model, supervisees pass through predictable stages or levels on their journey from apprentices to masters (Stoltenberg & Delworth, 1987). Beginning interns may lack confidence and are dependent on the supervisor for advice and direction. At this early stage, interns often are very cautious and concerned about how to do things the right way, and may not have much insight into their own behavior or its potential impact.

With some experience, many interns begin to experience a conflict between dependence and autonomy. Feelings of confidence are quickly replaced by feelings of being overwhelmed. Supervisors and supervisees may have disagreements over the "correct" way to handle different situations.

Eventually, a firmer sense of identity and self-confidence evolves. The intern becomes more tolerant of differences and is increasingly more flexible in choosing approaches to solve problems. In addition, the supervisee seeks help and advice without feeling overly dependent on the supervisor.

Excellent supervisors change their behaviors (from advice giving to support) according to the needs and developmental level of their supervisees. They do not overreact to predictable conflicts and are patient with interns' early feelings of helplessness and dependence.

Model Synthesis

The personal style of the supervisor and intern, the supervisor's and the intern's characteristics, and previous experiences with supervisors will all interact in choosing a particular model of supervision. The best supervisors may be those who have been able to manage a flexible blending of the above (and other) perspectives, thereby taking an integrated approach to supervision, and one that can be adapted to meet the unique needs of individual interns. The most effective supervisors provide structured resources for interns in terms of goals and learning experiences while making sure to emphasize the personal impact of the intern on clinical success. The personal impact of the intern is a function of his or her ability to carry interventions through to successful completion through careful planning, evaluation, and coordination of the efforts of other persons involved. Experience has indicated that powerful technologies are wasted if psychologists cannot gain the investment of staff members and families in their intervention efforts. Gaining such investment is rarely dependent simply on the power of a good idea. Interns (and supervisors!) must have the interpersonal skills and social awareness to attract and maintain collaborations.

BEST PRACTICES

Assessment of Supervisory Skills

In addition to meeting the requirements for being a supervisor from the relevant professional organizations (e.g., school psychologists with continuing credentials; doctoral, licensed psychologists), supervisors should reflect upon their own supervisory skills and experience in order to prepare for the supervisory role. Appendix A is a suggested format for rating the supervisor's skills. Completing this assessment may provide supervisors with some important learning goals and information about blind spots in their own behaviors.

For example, the supervisor's comfort with allowing independence among interns is very important to analyze. Interns (Kramer, Conoley, Bischoff, & Benes, 1991) often describe supervisors as too laissez-faire (i.e., tending to allow for too much independence) or as too controlling. Given the developmental issues raised above (Stoltenberg & Delworth, 1987), it is vital that supervisors be aware of and evaluate their general stance toward the autonomy of the intern and the ways this stance may be modified according to intern preferences and competencies, or client situations.

Evaluating Intern Skills

A successful supervisor must develop a number of strategies for evaluating the level of intern skills so that appropriate teaching plans can be made and assessment activities accomplished. The critical issues for the supervisor to investigate are as follows.

1. Competence: Does the intern have the necessary skills, techniques, and knowledge to take appropriate action? Psychologists must be expert in implementing and interpreting numerous assessment procedures, performing direct interventions with children and their families such as counseling and behavior modification, and indirect interventions (e.g., consultation, research, and program evaluation).

2. Emotional awareness: Can the intern use his or her own emotions and reactions to understand and empathize with others? Supervisors must target interns' communication skills, interpersonal relationships, and personal stability as potential areas for change if problems are apparent.

3. Identity: Does the intern develop a consistent way of thinking about problems and planning actions?

4. Respect for individual differences: Does the intern make an active effort to understand and appreciate cultural or ethnic (or other) differences? Is basic respect present for alternative lifestyles and choices?

5. Purpose and direction: Can the supervisee formulate plans, identify short- and long-term goals, and monitor progress? Research training should have prepared interns to conduct $N = 1$ studies, collect data, and evaluate outcomes. Intervention or assessment without outcome-based evaluation is questionable practice.

6. Autonomy: Can the supervisee make choices and decisions independently? Is there an appropriate degree of self-management?

7. Ethics: Are ethical issues, values, and standards integrated into practice?

8. Motivation: Is the intern internally motivated, finding work rewarding and meaningful?

Making informed judgments along these dimensions will demand that the supervisor meet individually with the intern, observe the intern's professional functioning, and collect evaluations from others who are directly involved with the intern. An evaluation instrument that may serve as a starting point in constructing an internship evaluation is reproduced as Appendix B. This instrument is completed twice each year. The completion of the rating form serves as a way for the supervisor and intern to discuss progress at the end of the first half of the internship and again near the end of the experience.

It is also of great importance to develop ways to provide ongoing feedback to interns and give them help in organizing their work. Appendix C is an example of a Progress Monitoring Sheet used to give interns information about their cases and about the success of their interventions. The form is designed to be completed in duplicate so the intern has a record of suggestions developed during supervision, and the supervisor has a record of what issues and strategies deserve follow-up attention.

Ethics and Equity Issues

School psychologists face enormously complex and often ambiguous ethical dilemmas. In addition, supervisors must clearly understand the boundaries that delimit supervisory relationships in terms of exploitation and equity (e.g., appropriate work expectations or gender equity issues).

INTERNS

Although the entire practice of psychology is governed by law and ethics, the practice of school psychology has additional demands from laws specific to education and the ethical dilemmas posed by continuous interactions with minor clients (Jacob-Timm & Hartshorne, 1998). It is clear that intern supervisors should always determine the intern's level of knowledge about current ethical standards and educational laws and regulations as well as associated state mental health laws. Supervisors must assess this knowledge at the very start of the internship experience, so interns can be given any needed information immediately.

Beyond knowledge, however, is the ability to apply these principles to daily decision making. Although research supporting the effectiveness of didactic training in ethics is mixed (Welfel, 1992), the efficacy of positive modeling by the supervisor and careful monitoring of the intern's behavior must be accepted as a powerful force influencing interns. Supervisors might find it useful to study Kitchener (1984) and Rest (1984) for information (beyond mere listings of principles) that is useful in developing the ethical decision making and moral development of their interns.

Rest (1984) suggests that an ethical person must have (a) empathy, (b) well-understood rationales for deciding which of the options in a dilemma is morally right or comes closest to one's ideals, (c) ways of selecting among competing values and motivations so that a plan of action can be made, and (d) the characteristics that allow plans of action to be implemented, such as resoluteness and perseverance.

Kitchener (1984) provides assistance for ethical decision making, especially for deciding among options. She delineates five critical ethical principles for the evaluation of ethical dilemmas in psychology. These principles are autonomy, beneficence, nonmaleficence, justice, and fidelity. Although each of these principles has many applications, a few examples suggest the richness of Kitchener's (1984) thinking.

Interns should know that a commitment to autonomy underlies our pledge of confidentiality and care in dealing with records. Respecting and promoting others' control of their lives is a key element of establishing therapeutic relationships. Dealing with autonomy concerns with children is quite sensitive. For example, how does the intern handle disclosures from adolescents that implicate family members as abusers but are unlikely to result in the child's removal from the home? How is confidentiality protected when so many professionals have a "need to know" about children?

Non-maleficence means a promise to "above all, do no harm" and beneficence is associated with psychology as a science and practice dedicated to promoting human welfare. Trainees and supervisors must examine their competencies, the potential negative impact of assessments and interventions, and the client's and client family's civil rights when choosing treatment and assessment options. Unfortunately, there is frequently a price associated with every positive change, and interns are often unaware that their interventions or assessments may inadvertently do harm. It is critical to be able to sort through the likely harm and good associated with our professional intrusions into other people's lives.

Justice means being dedicated to fairness. School psychologists are necessarily concerned that each child has access to an appropriate education. How are situations resolved when one child's access is deleterious to another's? Can a common good be discerned in every situation?

Finally, fidelity refers to honesty in fulfilling commitments and being consistent. Fidelity is owed to children, teachers, school systems, families, and colleagues, and also to personal ethics.

Each of these guiding principles may place differing and sometimes competing demands upon the intern, often with compelling rationales. Too often supervisors and interns may believe that knowing the lists of ethical principles from the National Association of School Psychologists (1997) and the American Psychological Association (1992) will suffice with respect to ethical competencies. Given the rising numbers of ethical complaints filed against psychologists, however, more attention to high-level ethical thinking seems warranted. In addition, ethical challenges raised by HIV-AIDS, teenage health and sexuality, culturally sensitive assessment and intervention efforts, and the changing expectations regarding school psychologists all suggest that ethical training is of critical importance.

Supervisors may appropriately anticipate that interns come to their sites with significant knowledge bases in ethics. The actual formation of ethical practice occurs, however, during intense practice. Internship is, therefore, a prime time to develop ethical frameworks that will be useful throughout a professional career.

SUPERVISORS

Supervisors have many ethical responsibilities toward their interns. Paramount among these may be the management of the supervisory relationship to ensure that it is equitable. All dual relationships (e.g., intimate friendships, joint business ventures) with supervisees are problematic (Kitchener, 1988) but sexual relationships are expressly forbidden (Bartell & Rubin, 1990; Pope, 1989). At the very least, the supervisor who engages in sexual relationships with interns has failed to model appropriate professional interactions and so has failed to fulfill an important element of his or her contract with the intern.

Sexual harassment and racial (and other) prejudice are present in most or all of our major societal institutions. Supervisors must be alert to even subtle instances of such in their own and their interns' behaviors. It may be useful for supervisors to consult the *Guidelines for Providers of Services to Ethnic, Linguistic, and Culturally Diverse Populations* (American Psychological Association, 1990).

Interns' Perspectives and Suggestions for Supervisors

In determining best practices in supervision, it is important to explore how interns feel about the process of supervision, including their expectations and what they value most and least about supervision and supervisors. These perspectives are helpful in facilitating the generation of specific suggestions for supervisors. The themes and suggestions outlined below come from four sources: (a) the interns in the Nebraska Consortium were asked to provide input regarding the quality of their internship experiences between 1986 and 1996 ($N = 90$); (b) the second author of the previous edition of this chapter (Conoley & Bahns, 1995) interviewed students who had completed field placements regarding their experience of being supervised ($N = 20$); (c) the second author of the present chapter solicited similar information from school psychology doctoral students at Texas A&M University who were involved in various supervised practicum experiences ($N = 10$); and (d) the authors consulted published empirical research and conceptual papers in the field of supervision.

Perhaps the most important message to be taken from the following discussion is that supervisors would be wise to elicit a careful consideration of these issues at the beginning of the supervisory relationship.

SUPERVISOR AVAILABILITY

Interns are sensitive to the accessibility of their supervisors. Even when they perceive the supervisor to be talented and competent, difficulties in contacting a supervisor during a critical period or in arranging for regular supervision result in poor evaluations and a diminished experience. Two hours each week of individual supervision must be given to the interns in addition to other group staffing and educational experiences (e.g., case presentations, workshops). Supervisors should be permitted to have only the number of interns who can be adequately served and must be well organized to have supervisory time available.

DEPENDENCE VERSUS INDEPENDENCE

Most interns seem to value a large amount of direction from supervisors, especially at the initial stages of the internship (per the developmental model described above). For example, many interns want assistance especially with understanding and conceptualizing cases, and prefer specific direction over general suggestions. On the other hand, interns do not appear to value authoritarian supervisors who insist on only one correct approach to clinical situations.

The bottom line may be this: interns value direction but want many options from which to choose, and do not want to be told *exactly* what to do. They desire supervision that helps them get "unstuck" and that forces them to think for themselves about clients. Of course, the extent to which interns desire dependence or independence is extremely variable, and should be determined by the supervisor on a case-by-case basis.

INTERN EXPECTATIONS

Briefly, interns generally expect that supervisors will be highly knowledgeable in both theory and practice, use a research-based framework to provide services, respect the intern's personal style of providing services, be supportive, and hold very high expectations for the interns. Supervisors are expected to help interns formulate hypotheses and construct case conceptualizations, in addition to exploring all possibilities or competing scenarios regarding clients and their treatment. Some interns especially value a highly structured approach to supervision and cases, and desire frequent feedback on competency and skill development. Further, interns expect the supervisor to be positive and encouraging, picking up on what the intern could have done differently in a case without being overly critical, judgmental, or negative.

CREATING A SAFE PLACE

Because many interns are anxious and insecure about providing services, and also about the ongoing evaluation that accompanies supervision, it is essential that the supervisor create a "safe place" in supervision, wherein personal and professional growth is enhanced and fear is minimized (Emerson, 1996). This can be accomplished by creating an environment conducive to trust and open communication, never putting interns down, using humor, involving interns in decision making, treating interns fairly and with respect, and ensuring confidentiality. Both the supervision literature and student responses indicate that constant support and persistent encouragement are very important to interns, and can help to enhance their self-confidence, thereby facilitating skill improvement. It may be helpful for supervisors to remember the "One for Two Rule": for every *one* correction or criticism the supervisor offers the intern, the supervisor should provide *two* compliments or positive statements. This may help in keeping the overall climate of supervision positive and supportive, even when the supervisor must give constructive criticism.

CULTURAL AWARENESS

Fukuyama (1994) discusses some of the issues in multicultural supervision with ethnic minority trainees. Of primary importance among minority interns is the feeling that neither they nor their cases are stereotyped by the supervisor. Further, minority interns feel supported when the supervisor expresses belief in the interns' abilities to work with and engage challenging clients, and when the supervisor initiates discussion of multicultural issues and expresses a general cultural awareness and sensitivity (e.g., acknowledging a religious holiday). In contrast, lack of awareness of cultural-specific norms and use of slang or stereotypes can severely harm the relationship between supervisor and intern, leaving the intern feeling hurt and insulted.

Of course, the expression of support, acceptance, and awareness is important to all interns, not just those who happen to be members of minority groups. Supervisors should be aware, however, that minority interns are often "one of a kind" at an internship placement and can experience all the unique stresses of such tokenism. This situation calls for special sensitivity.

TIME MANAGEMENT

Although all interns expect to work hard, most are unprepared for the intensity of the internship experience. Interns commonly report feeling overwhelmed by the demands on their time and unaware that they should take some responsibility for controlling their assignments. They report feeling unwilling to refuse any assignment. This occurs sometimes because they (ambitiously) want to learn everything and sometimes because they fear a negative reaction if they object or hesitate. Very often they lack basic time management and assertiveness skills. These predictable problems sometimes result in interns' engaging in activities that are not appropriate for their role. Not only do they fail to set limits with supervisors, they set no limits with anyone else! Supervisors should be prepared to teach these professional management skills to interns by their own example.

EXPLOITATION OF SKILLS

Some institutions use interns as cheap sources of labor for repetitive or unpopular tasks without a concomitant commitment to training. This attitude is easily discerned by the interns, who resent that their work for the organization is not met with a return of training opportunities. Internships are organized training experiences, not mere on-the-job experiences. This basic fact about internships is often not well understood at the internship site. Careful cooperation between university and internship faculty must be maintained to be sure that everyone stays invested in *teaching* the interns, not merely using them to ease the strain of overflowing caseloads.

NEGATIVE SUPERVISOR ATTITUDES

Interns are disillusioned by supervisors who are pessimistic or cynical about professional functioning. Often, under the guise of teaching the intern what the real world is like, supervisors fail to model enthusiasm and optimism in their work. Supervisors may act like victims in their systems rather than instructing interns on how to approach the long and difficult processes of organizational change. Interns may learn more negative information than positive steps to create change.

PERSONAL CONCERNS

The 9-month internship for educational specialist students or the 12-month experience for doctoral students occurs in the context of family, financial, health, and academic concerns for many interns. These and other concerns warrant attention from supervisors. Although problems in these areas can rarely be solved by supervisors, all interns seem to appreciate being known in their complexity by their supervisors. Some mutual appreciation of what the training site is offering the intern and what the intern is sacrificing to finish the demanding degree program can help both sides keep ultimate goals in view.

SUMMARY

The internship experience is often regarded as the pinnacle of graduate training in school psychology. Indeed, it represents the culmination of years of coursework, practicum experience, and research, and offers interns the opportunity to integrate all they have learned with the ultimate purpose of refining clinical skills and promoting ethical practice. Supervisor competence and commitment, therefore, are critical. All supervisors must be well versed both in current guidelines from their professional organizations (American Psychological Association, 1981, 1992; National Association of School Psychologists, 1994, 1997) that speak to basic expectations regarding state-of-the-art training of interns, and in the research supporting supervisory processes (Crespi & Lopez, 1998; Robiner & Schofield, 1990). Furthermore, they must be cognizant of their own competencies in assuming an educative role with others. These competencies include knowledge, ethics, patience, and personal functioning. The exact sequence of activities offered to interns should be well articulated and responsive to the intern's strengths and weaknesses and academic program expectations. Interns should be offered experiences in the best of professional functioning if the field is to progress. Tired, old, and invalid test batteries, and treatment methods known to have limited effectiveness, should not be imposed on interns, who may arrive at their sites with information new and useful to the supervisors. Enthusiastic interns should be schooled in the complexities of working in systems that have yet to understand the great potential of psychology.

The vitality of psychology in the schools depends on every supervisor who mentors an intern to high levels of skill, compassion, and the certainty that school psychologists can make a huge contribution to children, families, and the educational enterprise.

ANNOTATED BIBLIOGRAPHY

Crespi, T. D., & Lopez, P. G. (1998). Practicum and internship supervision in the schools: Standards and considerations for school psychology supervisors. *Clinical Supervisor, 17*, 113–126.

Provides information regarding supervision specific to the field of school psychology, in terms of internship

objectives, supervisor qualifications, training responsibilities, and supervisory evaluation. Includes useful guidelines for the provision of supervisory services in detail beyond the scope of the present chapter, in addition to sample supervisor and intern evaluation forms.

Fukuyama, M. A. (1994). Critical incidents in multicultural counseling supervision: A phenomenological approach to supervision research. *Counselor Education and Supervision, 34,* 142–151.
Discusses the importance of cultural awareness and other competencies that must be demonstrated by supervisors working with ethnic minority interns. Fukuyama provides examples of what supervisors can do to make their interns feel accepted and supported, and offers suggestions for making supervision more culturally sensitive.

Jacob-Timm, S., & Hartshorne, T. S. (1998). *Ethics and law for school psychologists* (3rd ed.). New York: Wiley.
The essential ethical and legal reference for students, teachers, practitioners, and supervisors in the field of school psychology. This updated, practical guide includes the 1997 revision of the National Association of School Psychologists' *Principles for Professional Ethics* and *Standards for the Provision of School Psychological Services*, in addition to the American Psychological Association's *Ethical Principles of Psychologists and Code of Conduct*. Numerous case studies are used to bring life to law and ethics, and coverage includes ethical and legal issues regarding assessment, therapy, consultation, and research.

National Association of School Psychologists. (1994). *Standards for training and field placement programs in school psychology.* Washington, DC: Author.
These standards reflect significant emphasis on knowledge-based and outcome-based training. Students should be prepared for the delivery of comprehensive, intervention-based services. One comprehensive standard for practica is included; practicum experiences are proposed in areas not previously required.

Stoltenberg, C. D., & Delworth, U. (1987). *Supervising counselors and therapists: A developmental approach.* San Francisco: Jossey-Bass.
Developmental levels of trainees are described over eight dimensions: intervention skills, assessment techniques, interpersonal assessment, client conceptualization, individual differences, theoretical orientation, treatment goals and plans, and professional ethics. Progress is traced by using three structures: awareness of self and others, motivation, and autonomy.

APPENDIX A

Self-Assessment of Supervisor Skills and Knowledge

	Needs				*Expert*
Teaching Skills					
Identify learning needs	1	2	3	4	5
Write learning goals	1	2	3	4	5
Devise instructional strategies	1	2	3	4	5
Present material didactically	1	2	3	4	5
Present material experientially to explain rationale of intervention	1	2	3	4	5
Evaluate learning	1	2	3	4	5
Comfort in authority role	1	2	3	4	5
Give constructive feedback	1	2	3	4	5
Intervention Skills					
Possess appropriate knowledge bases	1	2	3	4	5
Establish rapport	1	2	3	4	5
Create motivation	1	2	3	4	5
Challenge existing knowledge and attitudes	1	2	3	4	5
Facilitate exploration of skills	1	2	3	4	5
Facilitate exploration of feelings	1	2	3	4	5
Knowledge of interpersonal dynamics	1	2	3	4	5
Model appropriate skills	1	2	3	4	5
Respond with flexibility	1	2	3	4	5
Integrate data into case conceptualization	1	2	3	4	5
Consultation Skills					
Assess problem situation	1	2	3	4	5
Provide alternative interventions or case conceptualizations	1	2	3	4	5
Facilitate brainstorming	1	2	3	4	5
Encourage choices, responsibility	1	2	3	4	5
Function in collegial, collaborative manner	1	2	3	4	5
Manage group/team process	1	2	3	4	5
Commitment to Ethics and Equity					
Knowledge of current ethical standards	1	2	3	4	5
Skills in application of ethics to complex situations	1	2	3	4	5
Skills in enhancing the moral development of interns	1	2	3	4	5
Commitment to creating nonexploitative relationships	1	2	3	4	5
Commitment to equal opportunity	1	2	3	4	5

The following questions may be helpful in framing some of the important issues.

1. In which supervisory role do you have the most experience? Teacher, consultant, counselor? In which do you have the least experience?
2. What is your preferred style?
3. What feedback have you received about your supervision? For example, do you over explain, are uninvolved, are too verbose, can give examples, are challenging as well as facilitative.
4. What strengths and limitations do you see in your supervision style? How might the strengths be used and the weaknesses be addressed?
5. With what types of learners (interns) are you most comfortable? Consider ethnic, cultural, racial, sexual preference, and disability groups when you reflect upon this answer.
6. Can you remember an event of effective supervision you experienced during your training? Do you remember an ineffective incident? Describe the critical dimensions of each.
7. What did you look for in a supervisor? What worked best for you?

APPENDIX B

Psychology Intern Evaluation
Nebraska Internship Consortium in Professional Psychology

Date of Evaluation ________________________

Intern ________________________

Training Director ________________________

Directions: The ratings of the intern should be based upon actual observation and/or reports from staff, clients, families, etc. Choose the number of the scale that best describes the intern's competence. A description of scale points is provided below.

1 - Competence is considered to be in need of further training. Intern seems to lack basic professional maturation in this area. Skill development seems doubtful.
2 - Competence is currently considered below average, but supervision and experience are expected to develop the skill. Close supervision is required.
3 - Competence is at an average level for functioning with moderate supervision.
4 - Competence is assessed to be above average suggesting only a minimal need for supervision.
5 - Competence is very well developed and reflects a capacity for independent functioning with little or no supervision required.
No data - Insufficient information to make a rating at this time.

Tucson, Arizona

OVERVIEW

The increasing complexity of society has placed greater demands upon the school, the school psychologist, and school psychological delivery programs to add to their repertoire of "traditional" services (Franklin & Duley, 1991). School psychological delivery programs that are predicated on situations such as refer-and-test models of service delivery, as school psychologists as gatekeepers for special education, as a search for pathology, or as a commitment to reactive versus preventive services and that perpetuate a "static" approach to delivery may find their future survival questionable. It is imperative that school psychologists make choices about matching professional services with the needs of the children and youth we serve and "enhance the likelihood of effective intervention" (Reschly & Grimes, 1990, p. 425). Oakland (1986) suggested that school psychologists work to ensure their services are cost-effective, have community support, and are beneficial beyond what occurs without school psychological services.

This updated chapter provides direction for school psychologists or individuals responsible for establishing or redesigning school psychological services delivery programs. It will include (a) a review of programs that work, (b) organizational considerations, (c) program administration and supervision, (d) comprehensive service delivery, and (e) considerations for the future.

BASIC CONSIDERATIONS

The National Association of School Psychologists (NASP) *Standards for the Provision of School Psychological Services* (National Association of School Psychologists, 1997b) provides the position of the Association "regarding the delivery of appropriate and comprehensive school psychological services." Individuals who are establishing or modifying existing school psychological services should possess a thorough working knowledge of these NASP *Standards*.

To successfully establish or modify a school psychological service delivery program, the school psychologist may benefit from sensitization to programs that work. What follows is a review of six award-winning innovative school psychology delivery programs, although there exist numerous other exceptional school psychology programs.

Beginning in 1982, Division 16 (School Psychology) of the American Psychological Association (APA) and NASP initiated an award to recognize exemplary school psychological service units (Telzrow, 1989). "The award represents a positive public citation for excellence in providing comprehensive psychological services in the school" (Telzrow, 1989, p. 59) and recognizes a psychology services unit that is "exemplary in the range and quality of services offered in the schools" (Division Spotlight, 1988). Recipients of the APA Division 16–NASP Award for Excellence have included Memphis (Tennessee) City Schools Mental Health Center (1982), Gwinnett County Schools Psychological Services (Lawrence, Georgia) (1985), Amphitheater Unified School District School Psychology Department (Tucson, Arizona) (1987), Broward County Schools Psychological Services and Section 504 Support Services (Florida) (1990), Cherry Creek School District Mental Health Team (Englewood, Colorado) (1990), and Cypress-Fairbanks Independent School District Psychological Services (Houston, Texas) (1990) (Telzrow, 1989; L. W. Roosa, personal communication, May 24, 1993). The Award of Excellence does not appear to have been bestowed since the 1990 recognitions (J. A. Cummings, personal communication, February 20, 2000; R. O'Donnell, personal communication, February 23, 2000). A description of each service unit follows.

MEMPHIS CITY SCHOOLS MENTAL HEALTH CENTER

The Memphis City Schools Mental Health Center (MCSMHC) is a service unit to the Memphis City Schools as well as an incorporated not-for-profit mental health center (Paavola, Hannah, & Nichol, 1989). The unit has been led by the director, who is a licensed psychologist with competencies in school psychology. The director has answered to the same associate superintendent as has special education, guidance, and research (Paavola et al., 1989). The MCSMHC has required each staff member to obtain a minimum of 50 staff development hours each year. The MCSMHC has provided mental health services that have included parent/teacher consultation, prevention activities, individual, family and group counseling, and psychological assessment (Nichol, 1993). Currently the MCSMHC provides services for 116,000 students and employs 48 school psychologists. Recently, the Memphis School District adopted an experimental program of fully coordinated support services using School Coordinating Teams articulated by Howard Adelman of the University of California-Los Angeles (Portner, 2000). The district established nine area teams, each headed by a school psychologist (J. Chapman, personal communication, May 2, 2000). The school psychologists support the new system because it de-emphasizes the most bureaucratic portions of their jobs. Approximately 60% of their time had been previously dedicated to student assessments. The new system will employ behavioral specialists to conduct student evaluations, allowing the school psychologists to provide more direct service and intervention to students, behavior modification, anger management, and individual counseling (Portner, 2000).

GWINNETT COUNTY SCHOOL PSYCHOLOGICAL SERVICES

Bush et al. (1989) reported that Gwinnett County in Lawrence, Georgia, has experienced tremendous growth in their student population without a concomitant increase in psychological services staff. Historically, the Gwinnett County School Psychological Services program has been responsible for assessment of students for possible eligibility for special education programs. This diagnostic model of service delivery was found to be "inadequate" owing to the increasingly diversified population. Following a needs assessment, the program formulated a more comprehensive model of services which combined traditional assessment functions with consultation activities. The mission of the program is to provide comprehensive psychological service. The program utilizes a school-based model of consultation proposed by Gutkin and Curtis (1982) with emphasis on collaborative problem solving and the use of student study teams (SST). The manual describing procedures for the SST was revised in 1997 and distributed to all schools. The Gwinnett County program is directed by a licensed/certified professional psychologist and uses a comprehensive evaluation process for psychologists that involves direct observation, analysis of reports, and a summative conference (D. Carter, personal communication, March 26, 2000) . Bush et al. (1989) reported that the program has established a goal to include research and publication. Also, by more effectively managing the assessments and focusing on prevention, the perceived role of the psychologists has changed from gate keeper of special education to that of child advocate with expertise in many areas.

AMPHITHEATER SCHOOL DISTRICT SCHOOL PSYCHOLOGY DEPARTMENT

The Amphitheater School District in Tucson, Arizona has a diverse population of 17,000 students and employs 14 school psychologists. The School Psychology Department head is a certified professional school psychologist and is licensed by the State Board of Psychologist Examiners, provides school psychological services to a district school, and reports to the Executive Director of Student Services. The program adheres to a model of behavioral consultation based upon the work of Bergan (1977). If initial consultation is not successful, or more formal intervention appears warranted, a SST generates alternative intervention strategies. The primary function of the school psychologist is advocacy for the student seeking solutions in the least restrictive setting (Franklin & Duley, 1991). The SST is an additional creative and dynamic problem-solving process using a multidisciplinary team approach. Each psychologist participates in research activities as well as the dissemination of applied research. The Amphitheater School Psychology Department through the use of a consultative model has utilized a growing research base across a number of fields of psychology to address concerns of students in an educational setting. The use of this model has led to a decrease in per capita referrals paired with an increase in student population. Recently a pilot project was implemented using Referral Question Consultation, an empirically based, generic problem-solving model (Batsche & Knoff, 1995), with a population of 1200 elementary students. This led to a further dramatic decrease in the number of students formally considered for special education eligibility. Through the commitment to provide systematic pre-intervention activities the school psychology staff has been better able to provide increased levels of behavioral consultation, direct service, in-service, and related efforts.

BROWARD COUNTY SCHOOLS PSYCHOLOGICAL SERVICES AND SECTION 504 SUPPORT SERVICES

The Broward County School District in Ft. Lauderdale, Florida, is the nation's fifth largest school system and serves a diverse population of more than 250,000 students and employs approximately 110 school psychologists (L. W. Roosa, personal communication, May 18, 2000). Psychological Services is a department within Student Support and Exceptional Student Education Services, which is a component of the Division of Instruction and Program Services. The director, who is an experienced school psychologist, administers the program and is responsible for the programmatic aspects of the services. The direct supervision of school psychologists is provided by Area Coordinators of Student Services, who are experienced school psychologists or social workers. The Psychological Service Department provides a comprehensive range of prevention and consultation activities. School psychologists participate on school-based child study or intervention assistance teams. Collaborative problem-solving consultation activities are available to teachers, principals, and parents. They also provide support to staff members and parents with regard to meeting the requirements of Section 504, participation in violence prevention initiatives, use of a computer database to monitor assessment cases, and delivery of ongoing professional development activities. The size of the department and the staff selection procedures provide for a diverse staff of school psychologists with expertise in low incidence handicaps (e.g., autism and traumatic brain injury) and bilingual evaluations. Bilingual psychologists have participated in the development of informal academic assessment instruments in both Creole and Spanish and have established training programs regarding issues related to second-language acquisition.

CHERRY CREEK SCHOOL DISTRICT MENTAL HEALTH TEAM

The Cherry Creek Schools Mental Health Team (CCMHT) consists of approximately 80 psychologists and social workers who serve a population of 40,000 students in a suburban area near Denver, Colorado (C. L. Lines, personal communication, May 30, 2000). The CCMHT pairs a psychologist and a social worker in most buildings as a mental health team. This team determines the needs of an individual school and tailors services to these identified needs. The CCMHT utilizes a comprehensive community approach to meet the needs of the individuals and systems it services and is committed to a preventive and early intervention model. The CCMHT is supervised by a school psychologist who also serves as the Director of Special Education and reports to the Executive Director of Student Achievement Services. Daily practice issues are overseen by the Facilitator of the Mental Health Team, who is a school psychologist. New staff receives mentoring and small group support. The CCMHT is actively involved in a safe schools district-wide initiative. The Team demonstrates a continued commitment to the training and supervision of future school psychologist practitioners and social workers. They offer a unique re-specialization program for clinical psychologists moving into school psychology. The CCMHT offers seminars and a group supervision model for school psychology interns and practicum students completing placements in the district. The CCMHT also demonstrates a strong commitment to the professional growth of its team members through monthly inservice trainings, peer consultation groups, and clinical supervision for state licensing, which foster individual and professional growth.

CYPRESS-FAIRBANKS INDEPENDENT SCHOOL DISTRICT DEPARTMENT OF PSYCHOLOGICAL SERVICES

The Cypress-Fairbanks Independent School District is located in a rapidly growing suburban area of Houston, Texas. It has grown from a student population of 7,000 in 1968 to 62,300 in 2000. The Department of Psychological Services consists of 17 psychologists and six interns in an APA-accredited training program. The Director of Psychological Services reports to the Assistant Superintendent of Student Services. The psychologists and interns work with the district's 60 educational diagnosticians who manage special education students and complete all psychological evaluations. When appropriate the psychological services staff completes the emotional and personality components of evaluations. The Department's involvement throughout the district has significantly expanded in response to the behavioral and emotional needs of the district's population. The Department's mandate is to "provide quality, broadly based psychological services to the entire school district through a comprehensive psychological service delivery system." Four main goals have been delineated to achieve this task: (a) encouraging programs and providing services that result in the prevention of mental health and educational difficulties; (b) emphasizing indirect services to large populations of students at risk and their families; (c) providing direct services to small targeted groups of students who are determined to be in most extreme risk of school failure due to emotional/behavioral factors, to the families of these students, and to staff who are responsible for their education; and (d) coordinating with and complimenting community mental health and educational systems. The staff demonstrates a commitment to continuing professional development through participation in the intern training program as site supervisors, weekly training colloquiums, and topic study groups. The psychologists are also encouraged to develop areas of professional expertise and present at professional meetings, workshops, and district inservices (K. A. Young, personal communication, April 25, 2000).

The innovative school psychological delivery systems appear to possess in aggregate the following characteristics:

1. Highly qualified generalist/specialist practitioners and a wide range of expertise within each department.
2. Delivery of expanded and comprehensive school psychological services to meet the needs of *all* students.
3. A commitment to pre-referral intervention/prevention activities.
4. The use of school-based collaborative consultation.
5. Linking assessment to instructional intervention rather than classification alone.
6. Articulating departmental successes.
7. Accountability through efficacy data.
8. Malleability and adaptability to ever changing demands.
9. Relevant continuing professional development.
10. Departmental autonomy and clinical supervision and evaluation by a school psychologist.
11. Involvement as consumers and conductors of research.
12. A commitment to the training of future school psychologist practitioners.

BEST PRACTICES

There is no unitary "ideal" delivery system of school psychological services. A best practices model requires careful consideration of numerous variables. This section reviews organizational considerations, program administration and supervision, and 10 basic components of a comprehensive continuum of service delivery for a successful school psychology program.

Organizational Considerations

Placement of the school psychology delivery program within a school district's organization pattern (Talley, 1990) is seen as a critical issue for consideration. Within district models include school psychology as a separate program, within special education services, within special education, and building based. School psychology as a separate department allows for greater professional autonomy and visibility to facilitate the delivery of comprehensive school psychological services. This model allows for practice less encumbered by traditional association with special education. The director may provide both administrative and clinical supervision and often reports to an assistant or associate superintendent. In another model of school psychology, service delivery staff reports to a director of student services who may or may not be a school psychologist. Some independence from special education may be available. However, there is seldom appropriate school psychology leadership, administration, or appropriate clinical supervision of practice. A third model is the school psychology program subsumed within the special education department. In some districts, school psychologists are chosen to direct the school psychology program, but often non-psychologists are in this supervisory role. Problems that might arise from the choice of a non-psychologist director can include a lack of knowledge of practice guidelines, professional standards and ethics, and the comprehensive nature of school psychological services that can be provided. Staunch advocacy for expanded school psychological services may also be absent. The fourth model of building-based school psychology provides for the assignment of a school psychologist to one school or based in one school or several schools. Supervision and evaluation of practice is provided by the building principal. In this model school psychologists generally lack appropriate clinical supervision and may experience a sense of isolation from other school psychologists. Talley (1990) outlined a fifth model described as regional service delivery that is often found in rural school districts where school psychologists are employed by a regional service center or cooperative.

Program Administration and Supervision

The provision of appropriate supervision of school psychologists is required by professional associations (American Psychological Association, 1981; National Association of School Psychologists, 1997b), desired by practitioners (Zins, Murphy, & Wess, 1989), and is an integral component to the success of a school psychology delivery program. NASP has proposed that supervision be made available to all practicing school psychologists "to an extent sufficient to ensure the provision of effective and accountable services" (National Association of School Psychologists, 1997b, p. 684). A ratio of one supervisor for every 10 school psychologists is suggested by NASP with an equivalent ratio being maintained for part-time supervisors and that school psychologists receive one hour per week of face-to-face supervision during the first 3 years of full-time employment (National Association of School Psychologists, 1997b). Following the first 3 years all school psychologists are to continue in supervision and/or peer review (National Association of School Psychologists, 1997b). A supervising school psychologist is defined by NASP as a professional psychologist who has been designated by an employing agency as an administrator responsible for school psychological services in the agency and has met credentialing requirements (National Association of School Psychologists, 1997b). Coursework or other training in the supervision of school personnel is seen as desirable (National Association of School Psychologists, 1997b) and needed (Ross & Goh, 1993).

APA suggests that supervision be provided by a doctoral school psychologist at a ratio of one supervisor per 15 full-time school psychology personnel, that all non-doctoral school psychologists should be supervised, and that all school psychology services staff should receive face-to-face supervision (American Psychological Association, 1981; Talley, 1990).

Although one might assume that these supervisory standards would be commonly followed by most employers, it is suggested that such a commitment to supervision continues to be the exception rather than the rule. Zins et al. (1989) have reported that less than one in four school psychologists actually received clinical supervision. Zins et al. (1989) reported that clinical supervision is often provided by individuals whose terminal degree was not in school psychology and fewer than 50% of supervision met NASP or APA professional practice standards.

The supervisor should be responsible for providing evaluation of the school psychologist practitioner using data pertaining to their personal effectiveness, as well as data pertaining to the effectiveness of the department as a whole. This evaluation should be both formative and summative. Such evaluation can assist the school psychologist practitioner in determining his or her current developmental levels and professional strengths and weaknesses (Knoff, 1986). It is also suggested the supervisor must assess the effectiveness of the service delivery by the department and determine the match with the needs of the local constituency. The nature, magnitude, and frequency of problematic situations within the schools seem to be changing at a rapid pace in most communities. Therefore, it continues to be the school psychologist practitioner's responsibility to assess these problematic situations and provide timely and appropriate intervention. The nature and breadth of these problems make it at times difficult, if not impossible, to possess every technical and practical skill to deal with every facet of practice demanded in the field (Knoff, 1986). It becomes the responsibility of the supervisor to match the practitioner's relative strength areas with the identified needs of the constituency. It is important for the supervisor of school psychologists to provide liaison activities with other professionals in related fields. Federal and state rules, regulations, and standards to which school psychologists must adhere may be different from those rules applied to practitioners in related areas. It may therefore be necessary for the supervisor to define these differences to appropriate agencies or private practitioners to facilitate the continued delivery of quality school psychological services.

It is believed that the supervisor of school psychologists is most effective when he or she provides supervision while simultaneously understanding those being supervised by providing comprehensive school psychological services. It is also believed that the supervisor of school psychologists must always be seen as striving for individual and departmental excellence while always keeping one foot in the camp of the school psychologist practitioner. Without such a frame of reference one's supervisory effectiveness can be greatly diminished (Franklin, 1989). It is suggested that any best practices model for school psychology services delivery would require adherence to the provision of appropriate school psychology practitioner supervision.

In the establishment or modification of a delivery program it is necessary that we recruit qualified practitioners. Although most school psychologist practitioners received training as generalists (Fagan, 1990b), there may be a need to recruit individuals within specialty training to include early childhood, neuropsychology, curriculum-based assessment, and bilingual skills. Prior to hiring a new school psychologist practitioner it may be useful for the department to assess its present needs and establish a profile for the replacement psychologist. The supply and demand gap for school psychologist practitioners appears to continue to be problematic given the "graying" of the profession (Connolly & Reschly, 1990; Curtis, Hunley, Walker, & Baker, 1999). Ongoing networking with state professional organizations and graduate training programs, the maintenance of competitive salary schedules, and a work environment that allows for school psychologists to use their diverse skills can improve both the quantity and quality of applicant pools of school psychologists. As individuals in training programs seek higher levels of required training and employment in more diverse practice settings (Fagan, 1990a), it is suggested that shortages of school psychologist practitioners will continue in the future.

The school psychology department should facilitate the establishment of short-term and long-range departmental direction through the use of strategic planning to include a needs assessment, a mission statement, and specific departmental goals and objectives with measurable criteria (Franklin & Wasserman, 1992; Talley, 1995). This process allows the department to know where it needs to go, how it plans to get there, and when it has arrived.

NASP (National Association of School Psychologists, 1997b) provides guidelines suggesting a ratio of at least one full-time school psychologist for each 1,000 children and youth served. NASP recognizes that the ratio may vary based upon the needs of children served, the type of program served, resources available, distance between schools, and other unique characteristics (National Association of School Psychologists, 1997b). School psychology programs should advocate at the state and local levels for practitioner-to-student ratios that allow for the delivery of comprehensive school psychological services.

In light of higher caseloads, shortages of funding in public education to provide appropriate compensation or appropriate salary increases, and increasing expectations upon school psychologist practitioners (Fagan, 1990a), retaining qualified practitioners will continue to be a demanding issue (Curtis et al., 1999). Issues surrounding burnout of school psychologist practitioners should also be given consideration (Huebner, 1992; Thomas, 1995).

Comprehensive Continuum of Service Delivery

It is suggested that all school psychological practice should be in full accordance with NASP *Principles for Professional Ethics* (National Association of School Psychologists, 1997a) and *Standards for the Provision of School Psychological Services* (National Association of School Psychologists, 1997b). One purpose of the *Standards* is to help ensure "the provision of a comprehensive continuum of services" by school psychologists to all students (National Association of School Psychologists, 1997b, p. 683).

CONSULTATION AND PRE-REFERRAL INTERVENTION

It appears that central to most successful school psychology delivery programs exists the use of problem solving behavioral consultation with parents, teachers, and students themselves. "The school psychologist usually does not personally provide the intervention," but provides guidance for those that do so (National Association of School Psychologists, 1997b). Behavioral consultation generally incorporates a four-stage process in which problem identification, problem analysis, plan implementation, and plan evaluation are effected to address student difficulties. Central to the concept of the consultation model is the collaborative interaction between the psychologist and the teacher to address student needs (Franklin & Duley, 1991). It is then hoped that these skills generalize across other cases within the educational setting. Therefore, the skills of the psychologist may be used more effectively as a mental health practitioner and team leader as opposed to a more reactive, psychometrically based practitioner (Franklin & Duley, 1991). Intervention assistance programs, first described by Chalfant, Pysh, and Moultrie (1979), provide an alternate consultation framework for the delivery of school psychological services (Ross, 1995). Batsche (1991) reported that consultation/intervention services can reduce special education placements by as much as 50% without adversely affecting the progress of individual students.

ASSESSMENT

Another significant component of school psychology service delivery may be psychological and psychoeducational assessment. School psychologist practitioners must employ non-biased multi-faceted comprehensive psychological and psychoeducational assessment of children and youth as appropriate according to current best practices (National Association of School Psychologists, 1997b). School psychologists should utilize a variety of observational, behavioral evaluation, interview, as well as the traditional use of both normative and criterion referenced instrumentation. All assessment should be linked to instructional intervention. Reschly (1988) cautioned that assessment for classification will be replaced by assessment for the expressed purpose of developing intervention to be implemented in the classroom. Direct assessment techniques such as curriculum-based assessment (CBA) are seen as important competencies for school psychologists (Reschly, 1988). Reschly and Ysseldyke (1995) suggested that as practitioners we are "*pushed* by problems in the current system to consider alternatives to conventional referral, assessment, classification, and placement practices" (p. 23).

DIRECT SERVICES

Direct services to students is traditionally seen "as techniques supplied in a face-to-face situation (e.g. individual/group counseling, classroom-based interventions, etc.) designed to enhance the mental health, behavior, personality, social competency, academic, or educational status of the student/client, or prevent difficulties in these areas" (National Association of

School Psychologists, 1997b, p. 689). Both individual and group counseling activities would fall within this heading. Recently, school psychologists are dealing with crisis intervention situations that cause the "interrupted day." Often the school psychologist is the front-line mental health professional within schools and is therefore called upon to provide intervention services on an as-needed basis. This creates friction between crisis needs and the demands of the existing caseload and mandated timelines.

PREVENTION

Primary and secondary prevention, rather than tertiary prevention (treatment), should also be seen at the heart of a successful school psychology delivery program. The use of primary prevention seeks to change the incidence of new referrals by intervening proactively before a disorder occurs (Hightower, Johnson, & Haffey, 1995). For example, competencies may be increased through education or environments may be modified to reduce or counteract harmful circumstances. Primary prevention efforts call for proactive, pre-emptive efforts to increase resiliency rather than attempting to reduce existing problems (Hightower et al., 1995). Secondary prevention is generally seen as early identification and intervention before problems become severe. This paradigm shift from treatment to prevention (Hightower et al., 1995) is seen as a critical component for practicing school psychologists who desire to provide a successful school psychology delivery program. The existing need for more school psychology services and the continuing shortage of school psychologist practitioners suggest the need for adoption of effective prevention programs (Hightower et al., 1995). School psychologists must continue to place their energy on the front end of the continuum with broad based prevention rather than on the back end with expensive reactive crisis intervention.

RESEARCH

NASP suggests that school psychologists "design, conduct, report, and utilize the results of research of a psychological and educational nature" (National Association of School Psychologists, 1997b, p. 690). Keith (1995) defined research as "activities designed to produce new scientific knowledge or to use the knowledge to improve school psychological practice" (p. 135). Keith (1995) stated the need for school psychologists to be competent consumers of research, to act as distributors of research, and to conduct research. For those conducting research, the use of quasi-experimental research, single case designs, reversal designs, and multiple baseline designs hold promise (Keith, 1988). It is suggested that school psychologists should be involved in one or more levels of research to bring about a quality school psychology delivery program. Stoner and Green (1992) suggested that 100% of a school psychologist's time should be involved in doing research in that practice and research should become one and the same.

Kratochwill, Schnaps, and Bissell (1985) described four general types of research in school psychology including historical research, descriptive research, passive-observational methods, and experimental research. For school psychologists who have not been actively involved in research or in the use of research findings, Franklin and Sabers (1987) have suggested that active participation in research is almost certain to be accompanied by additional learning and professional development. Reading and discussing the literature during the planning stages of a study are likely to produce a better informed practitioner. The credibility one gains for self, the service unit, and the district should not be minimized. In this day of static or decreasing budgets for school psychology it becomes more important for the practicing school psychologist to maintain high visibility and become more valued. The school psychologist as researcher can become more valuable both as disseminator of research findings and as one who can investigate questions needing answers.

Anything that is worth doing within a school setting warrants consideration for sharing with fellow professionals. This "sharing" may take the form of oral presentations to district staff, presentations to local, state, or national professional groups, articles in state and regional publications, book chapters, or national refereed journals. "If it is worth doing, it is worth telling your fellow psychologists about it" (Franklin & Sabers, 1987, p.8). By way of example, during routine assessment, Franklin (1983) observed consistently lower scores on a subtest of a commonly utilized individually administered reading achievement test. This concern led to a decision to study this subtest. Issues surrounding design, method, and analysis were resolved through consultation with colleagues at a local university. This study led to an article based on data gathered as part of routine re-evaluations of a relatively small number of students. The reading subtest was subsequently modified by the instrument's author. This revision led Franklin, Fullilove, and Sabers (1985) to evaluate the author's modifications. Again, this research was accomplished as part of a routine pre-post testing battery for development of individual education plans, and incorporated a school psychology practicum student.

More recently a group of school psychologists and a doctoral intern observed disparity in standard scores for writing subtests of an individually administered achievement battery (Franklin, McHale, Kapp, & Sabers, 1999). After consultation with a colleague at a local university, existing data were analyzed and the results supported the observations of the practitioners. These findings led to a modification of special education eligibility decisions by multidisciplinary teams for students with written language deficits.

LIAISON AND COORDINATION

NASP advocates that school psychologists establish and maintain relationships with other professionals who provide services to children and families and "collaborate with these professionals in prevention, assessment, and intervention efforts as necessary" (National Association of School Psychologists, 1997b, p. 688). School psychologists can assist in coordinating the services of mental health providers from other agencies to provide a continuum of service for students (National Association of School Psychologists, 1997b). It is suggested that these liaison and coordinating roles will become increasingly important (Sheridan, 1995) as children and families lack access to private health insurance or managed health care programs.

SUPERVISION, TRAINING, AND MENTORSHIP

School psychology departments can contribute substantially to training and development of new school psychologists. Introductory school psychology students, practicum students, and internship students need to observe the existing expertise of school psychology practitioners who need to keep current with the theory and research that students bring with them. It is also important for practitioners to work with university trainers in the area of supervision of students participating in school psychology practica and internships (Conoley & Bahns, 1995). These activities help ensure the existence of a future pool of quality school psychologist practitioners (Franklin, 1995). It is suggested that new practitioners within school districts should be assigned mentors to assist in shepherding them into the politics and nuances of the school district and assisting with professional issues.

CONTINUING PROFESSIONAL DEVELOPMENT

There is a constant need for information that can, in part, be met through the provision of continuing education and professional training for the school psychologist practitioner. This may be accomplished through the dissemination of information between professionals within the department, contracting with experts for inservice, and through the participation of practitioners in conferences and workshops (Franklin, 1989). McKee, Witt, Elliott, Pardue, and Judycki (1987) suggested that talking to colleagues, exploring local needs, and requesting and sharing specific information may be as useful in obtaining information as more expensive solutions such as employing outside consultants, attending workshops, and using professional development materials. It may be necessary to advocate for continuing professional education and professional training activities for school psychologist practitioners.

"The practice of school psychology has and will continue to undergo significant changes as new knowledge and technological advances are introduced" (National Association of School Psychologists, 1997b, pp. 690–691). It will therefore be necessary for the school psychologist practitioner to remain knowledgeable regarding these changes. School psychology service programs that require or encourage school psychologist practitioners to acquire and maintain credentialing by the National School Psychology Certification System (National Association of School Psychologists, 1988) assist in the continued training and honing of existing skills of its practitioners. Continuing training and the reinforcement of existing skills are critical to the maintenance of quality school psychology delivery programs (Franklin, 1989, 1995).

ACCOUNTABILITY

Accountability of the service delivery program is an important component as well (National Association of School Psychologists, 1997b). Zins (1984, p. 58) defined accountability as an

> evaluative effort designed to gather systematically information relevant to the performance assessment of school psychologists. It enables them to demonstrate the effectiveness of their services to others, and it provides an evaluation of how well they have met their performance objectives. It is concerned with both quantitative and qualitative aspects of practice and addresses both individuals and groups. It is particularly useful in improving service delivery and enhancing professional development.

Batsche (1991) suggested that school psychologists collect data regarding efficacy related to costs, consumer satisfaction, as well as the effectiveness of service delivery. "If you are a supervisor or a school psychologist in a district hard hit by financial difficulties, ask yourself whether or not you are providing information that convinces superintendents and boards of education of the worth of school psychological services" (Batsche, 1991, p.2). In the Minneapolis, Minnesota, Psychological Services Program, accountability data brought about modifications in school psychology practice as a function of the outcome of the accountability system (Canter, 1991). As individual practitioners and as a profession we cannot ignore the need to regularly evaluate our services (Zins, 1990). Providing accountability data must become a routine component of school psychological services.

HIGH VISIBILITY

It is important to report the accomplishments of the school psychology department to the teachers, administrators, governing board members, and constituents of the district (Franklin, 1989). Maintaining high visibility for a successful school psychology delivery program can facilitate future support for additional staff positions, the provision of continuing education and professional training, and the delivery of "non-traditional" practice opportunities for the school psychologist (Franklin, 1989). Public image must be seen as a major factor in the role of the school psychologist and the services that are provided (Kelly, 1990, 1995). The following quote, attributed to the late Congressman Adam Clayton Powell, that "you will never hear any music if you don't blow your own horn" (K. P. Dwyer, personal communication, March 8, 1994) should be seriously considered by school psychologist practitioners.

Future Considerations

Hutton, Dubes, and Muir (1992) reported that school psychologists spend 40–60% of their time in assessment activities. Will (1988) suggests that the traditional role of school psychologists as gate keepers for the entry to special education and re-entry to regular education program needs to shift from reactive to proactive in which learning and instructional problems are presented. "This shift will require greater emphasis on instructional variables that include the curriculum, task features, teaching functions, and instructionally based assessment procedures" (Will, 1988, p. 478).

Outsourcing caused consternation for the Amphitheater School District School Psychology Department. An advisory committee, created by the Governing Board to investigate possible budget reductions, determined that disbanding the Department and outsourcing all assessment services required by federal and state mandates would reduce expenditures by a seemingly significant, and tempting, factor. However, a carefully documented study that established not only the engaged time for assessment but also other activities required by statute recalculated the cost of outsourcing given actual contractual arrangements with local and regional practitioners and halved projected reductions. The Department established in a presentation to the Governing Board that outsourcing would prove far more costly in the long run although initial savings may be realized. Without continued utilization of a pre-intervention consultation model, requests for assessment would skyrocket, as had already occurred across other disciplines that had attempted contracted services. Further, the Department advocated that the completion of merely mandated assessments did not provide a coordinated and organized comprehensive continuum of services advocated by NASP (National Association of School Psychologists, 1997b) and as a delivery model (certainly far from best practice) would likely increase costly due process hearings and litigation. To date, that advocacy has been successful and outsourcing has not been attempted.

Reschly (1988, p. 472) believed that the "character of school psychology at the dawn of the twenty-first century will be markedly influenced by how we manage the challenge of special education reform and the necessary revolution." Kavaleski (1988, p. 483) stated that school psychologists have a unique opportunity to alter contingencies that influence their own practice. Accepting this challenge can lead to the establishment of school psychology in a reformed system. Ignoring the opportunity will lead at best to business as usual and at most to the demise of a discipline.

As school psychological service delivery programs continue to experience static or declining budgets, five issues will demand scrutiny:

1. Continuing efforts to overcome resistance by school psychologists, teachers, and administrators as practitioner roles change from refer-and-test to pre-referral intervention and prevention.
2. The need to preserve school-based school psychologist positions (National Association of School Psychologists, 1993) and avoid "outsourcing" (National Association of School Psychologists, 1999).
3. The provision of efficacy data for school psychological services (Batsche, 1991). NASP urges school psychologists to empirically evaluate the cost effectiveness of current models of service and to establish on-going program evaluation (National Association of School Psychologists, 1999).
4. Attracting and retaining qualified school psychologist practitioners.
5. The hiring and utilization of individuals with less comprehensive training as educational diagnosticians or psychometrists under the direction of school psychology.

SUMMARY

As school psychological delivery programs are asked to constantly re-examine their roles, functions, and skills, they must resist the temptation to remain locked into models of delivery that are "comfortable." There exists no single best way to deliver effective school psychological services. However, the NASP *Standards for the Provision of School Psychological Services* (National Association of School Psychologists, 1997b) provides exceptional direction for those who are planning or modifying existing school psychology delivery programs. This chapter reviewed organizational considerations, program administration and supervision, and 10 components of a comprehensive continuum of service delivery for a successful school psychology program. A review of six innovative award-winning school psychology programs indicates that they appear to possess in aggregate a series of characteristics. These characteristics included (a) highly qualified practitioners and a wide range of expertise within each department, (b) the delivery of comprehensive services to *all* students, (c) a commitment to pre-referral intervention/prevention activities, (d) the use of school-based collaborative consultation and pre-referral intervention, (e) linking assessment to intervention, (f) articulating departmental successes, (g) accountability through efficacy data, (h) malleability and adaptability to ever changing demands, (i) continuing professional development, (j) departmental autonomy and supervision by a school psychologist, (k) involvement in research, and (l) a commitment to training future school psychologist practitioners.

It is hoped that school psychology services delivery programs that are fixed on narrow roles and functions for school psychologist practitioners will continue to strive to move from what is "real" to what may be seen as more "ideal" (Stewart, 1986).

11 Best Practices in Evaluating Psychoeducational Services Based on Student Outcome Data

Kimberly A. Gibbons
St. Croix River Education District
Michelle M. Shinn
University of Oregon

OVERVIEW

It is no secret that significant changes have occurred in the past decade with respect to how school psychological services are delivered. The role of the school psychologist has, and still is, evolving from that of gatekeeper to that of a scientist-practitioner and/or problem-solver (Deno, 1995; Reschly & Ysseldyke, 1995). A literature review of just the past decade will produce countless numbers of documents calling for, and describing changes, in the *services* provided by the school psychologist, including this book and the previous edition (Thomas & Grimes, 1995). These same publications also express the need for school psychologists to *evaluate the effectiveness of their services*, including documentation of improved student outcomes as the criterion for success (Reschly, 1995).

However, even with a continued and almost relentless emphasis on accountability in education and school psychology, there is *limited* information about the use of student outcome data to evaluate the effectiveness of the services provided by school psychologists. Of the current methods being used to evaluate effectiveness of services provided, outcome data appear to be collected the *least*. In the most recent survey of school psychology accountability practices, Fairchild and Zins (1992) found that of the respondents who reported collecting some type of accountability data, over 80% reported using a tabulation method, over one-half reported using a time analysis, and one-third reported the use of rating scales. Fewer than 10% of respondents reported writing goal statements or collecting any measures of behavioral change. Even with the increased emphasis on accountability, Fairchild and Zins (1992) found that these data had not changed since the original survey was completed in 1984 (Zins & Fairchild, 1986). There were no statistically significant changes in the percent of respondents from the 1991 or 1984 survey engaging in any type of accountability activities. Unfortunately, this survey is almost a decade old. One would be hard pressed to find current published evidence documenting the effectiveness of psychological and/or educational services using student outcome data.

Therefore, following a brief discussion of the most common methods used to evaluate school psychological services and limitations associated with these methods, a majority of this chapter will be devoted to providing practitioners with viable methods of using student outcome data to improve psychoeducational services to students with and without disabilities.

Current Methods of Evaluating Effectiveness

Tabulation, time analyses, and surveys (Canter, 1991; Fairchild & Zins, 1992; Fairchild & Seeley, 1996; Keith, Brown, & Oberman, 1992; Tomlinson, 1973) have been the most widely used methods to evaluate the effectiveness of psychoeducational services. Tabulation and time analyses are collected by having a school psychologist keep a log describing the types of services they provide and the amount of time spent in certain activities (Canter, 1991; Fairchild & Zins, 1992). Time analyses allow practitioners to monitor the amount of time they spend by activity and examine any changes in service delivery that occur either as a result of personal goals or departmental goals (Canter, 1991). However, it could be argued that such methods do not measure effectiveness at all.

Surveys also are commonly used by school psychologists to collect information about the perceived effectiveness of their services and ratings of personal characteristics and professional skills. In most cases, surveys are developed by the school psychologist to solicit feedback regarding topics such as interpersonal skills, ability to communicate, timeliness and follow through, availability for consultation, work habits, and the effectiveness of the recommendations they provide to teachers (Fairchild & Seeley, 1996; Keith, Brown, & Oberman, 1992; Tomlinson, 1973). Surveys typically include a series of questions, either open-ended or with a rating scale, completed by teachers, students, administrators, and parents.

Beyond time analyses and surveys, school psychologists also evaluate the effectiveness of their services by collecting outcome data. The most common outcome is that of student improvement over time as a result of involvement by a school psychologist. More formally, outcome data are intended to provide information about the behavioral changes that occur as a result of the services provided by the school psychologist (Fairchild & Zins, 1992; Tomlinson, 1973). Measurable increases in grades, acquisition of particular skills, and increases in reading achievement (Canter, 1991) have been used to demonstrate the effectiveness of involvement by a school psychologist.

Barriers to Evaluating the Effectiveness of Psychological and Educational Services

Perhaps the biggest barriers to collecting student outcome data to evaluate service effectiveness are the challenges involved in identifying *what* to measure and *methods* of collecting data (Fairchild & Zins, 1992). Almost 43% of the respondents in Fairchild and Zin's 1992 survey reported unfamiliarity with accountability procedures as a significant barrier to collecting any type of accountability data. Identifying what to measure can be overwhelming when we consider the number of different services provided by a school psychologist, including assessment, counseling, and consultation for academic, behavioral, social, and emotional concerns (Fairchild & Seeley, 1996). In addition, the effects of psychoeducational interventions have been considered by some to be global and less tangible than measures of academic performance and therefore less amenable to objective measurement (Tomlinson, 1973). However, the above-mentioned barriers can be overcome.

BEST PRACTICES IN EVALUATING PSYCHOEDUCATIONAL SERVICES

Best practices in evaluating psychoeducational services by using outcome data include the following steps: (a) developing clearly defined goals, (b) determining performance indicators of student performance, (c) describing the relationship between psychoeducational services and goals, (d) focusing on collaboration and teamwork, and (e) evaluating progress toward goals. Each of these steps is described in detail below, and a case study has been included to illustrate implementation of the steps.

Develop Clearly Defined Goals

"We did not find a single case in the literature where student learning increased but had not been a central goal."

— Joyce, Wolf, and Calhoun (1993)

The first step in evaluating psychoeducational services for the district is to develop clearly defined goals that are linked to student outcome data. However, most goals in education are rarely linked to student achievement, seldom challenge the basic elements of practice (McGonagill, 1992), and can be vague and difficult to measure. For exampl , many school districts have as a goal that all children will enter school ready to learn. This goal has many different meanings depending on who is interpreting it. A classroom teacher may interpret it to mean that children will come to school with the prerequisite knowledge and background and experiences to benefit from instruction. The school nurse may believe that it means students are well rested, amply nourished, and up-to-date on all vaccinations. The school psychologist may believe that it means that students are emotionally mature enough to stay on task during instruction and interact appropriately with peers.

Whatever the interpretation, it is paramount that goals are identified in such a manner that the goals are clear and measurable. According to Rosenholtz (1989), clearly specified goals are important for four reasons. First, specific goals help convey a message directly to educators that students are capable of improvement. Second, specific goals provide a basis for rational decision making. Third, specific goals enable teachers to gauge their success and make changes in instruction when progress is not satisfactory. Finally, specific goals promote professional dialogue.

By using the ready-to-learn example cited previously, one clearly defined goal may be that students enter school with a basic knowledge of print (i.e., knowing what and where the beginning and the ending of a book is, understanding the concept of reading left to right, knowing the top and bottom of the page). A goal of this type is objective and easily measured, therefore making it easier to make statements about student improvement based on outcomes.

Determine Performance Indicators of Student Performance

"What gets measured gets done."

—Peters (1987)

Once a goal is clearly defined, a determination needs to be made as to how student performance will be measured. Deno (1986) suggests that five criteria should be met when selecting a performance measure. First, the measure should be a reliable and valid indicator of student achievement or behavior. Second, the measure should be simple, efficient, and of short duration to facilitate frequent administration by teachers. Third, the measure should provide assessment information that helps teachers plan better instruction. Fourth, the measure should be sensitive to the improvement of student achievement and/or behavior over time. Fifth, teachers, parents, and professionals should easily understand both the resulting data and the measurement process. By using performance criteria that meet these criteria will help ensure that goals can be evaluated in a formative manner and that interventions can be implemented when student progress is unsatisfactory.

Traditionally, progress has been measured by using published, norm-referenced tests of achievement. These measures typically are not sensitive to short-term changes in student improvement, making them difficult to use as a formative evaluation tool (Marston, 1989). An alternative to published, norm-referenced tests of achievement is Curriculum-Based Measures (CBM). In basic skill areas, CBM are valid and reliable performance indicators that can be used as a formative progress monitoring tool (Shinn, 1989).

Describe the Relationship Between Psychoeducational Services and Goals

The trend in school psychology service delivery has moved away from assessment for diagnosis and classification of individual students toward a focus of assessment for the purposes of prevention and intervention to provide positive outcomes for all students. This change in service delivery provides a mechanism for school psychologists to assist education and state agencies in restructuring schools in positive ways. For example, school psychologists can indirectly impact student achievement by providing instructional and behavioral consultation, advocating for data-based practices, promoting research-based curricula, and assisting schools in setting up continuous and frequent measurement systems for all students.

However, when school psychologists take on the challenge of prevention and intervention, there should be a direct relationship between their roles and responsibilities and the goals identified by the system (i.e., individual school, district, or cooperative districts). Consequently, to effectively evaluate school psychology services using student outcome data, there must be a clear relationship between the system goals and the role of the school psychologist. To make this relationship clear, school districts should develop job descriptions that clearly state the district goals, roles and responsibilities of the school psychologists, percentage of time allocated for each responsibility, and outcome indicators of success.

When restructuring school psychology service delivery, administrators and teachers need to have input in the process and the definitions of roles and responsibilities. If a school district is committed to reaching its goals by restructuring psychoeducational services, then it is crucial that school administrators support school psychologists in their new roles. Clearly, if school psychologists are to engage in alternative activities, then there has to be an awareness and understanding that they will not spend the majority of their time engaging in more traditional activities. For example, the Minneapolis Public Schools found that by switching to a problem-solving service-delivery model using CBM, school psychologists provided more consultation, more direct intervention services, and spent less time in assessment services primarily to determine eligibility (Canter, 1991). Once school psychology services have been clearly defined, the school principal and the school psychologist should meet with teachers and support staff to outline the service-delivery model.

Focus on Collaboration and Teamwork

"Teams get results."

—Katzenbach & Smith (1993)

Obtaining results depends on the interdependency between collaboration and goals. Though teamwork is fundamental in this scheme, "it is the means, not the end" (Katzenbach & Smith, 1993, p.12). Obviously, school psychology services in isolation may not impact student outcomes in a significant way. Ultimately, it is the interaction between a number of variables that will have the most significant impact on student outcomes. For example, suppose a school district sets a goal that all children will read at grade level by the end of the academic year. Many factors will influence whether this goal will be met. These factors include choice of curriculum, instructional strategies, consultative support to teachers, data-based decision making, and administrative support. Teaching staff will need to examine the reading research and determine the core knowledge and skills students need to learn at each grade level. The district's curriculum committee will need to select a well-designed curriculum that includes the core knowledge and skills students need to learn.

The school psychologist may assist teaching staff in administering screening assessments for the purpose of determining instructional groups. Teachers and support staff are responsible for teaching the curriculum by using well-designed instructional strategies. The school psychologist may assist teachers in setting up a frequent and direct assessment system to monitor student progress. Principals need to allocate common time for teachers to prepare and review student progress with other teachers from their grade level. Finally, the school psychologist may meet with grade-level teams to review student progress and design individual or group interventions when progress is not satisfactory. School psychology services play an important role in determining whether student goals are met, but the key factor is the effectiveness of the "educational team" (Schmoker, 1996).

The previous example illustrates the complex work of teaching and obtaining results. Teaching "cannot be accomplished by even the most knowledgeable individuals working alone" (Little, 1990, p. 520). Evidence for the benefits of effective collaboration are overwhelming. Little (1990) found a strong relationship between the correct kind of collegiality and improvements for both teachers and students. These improvements included remarkable gains in student achievement, higher-quality solutions to problems, the ability to examine and test new ideas, methods, and materials, and an expanded pool of ideas, materials, and methods.

Schools are encouraged to establish collaborative teams at each building and individual grade levels for the sole purpose of reviewing progress toward goals and making adjustments in instruction in response to student data. The key element in collaborative teams is a focus on the end result (i.e., student achievement) and data-based decision making. The combination of goals and teamwork is essential to student performance. School psychologists, along with other building administrators, play a key role in working with teaching and support staff to continually focus on the identified goals and help groups work together in reaching the goal.

Evaluate Progress Toward Goals

"Assessment as a basis for formative evaluation contributes most significantly to problem solution."

— Deno (1995)

Once goals have been identified and a plan for reaching the goals has been developed, evaluation of progress toward goals should be conducted by using frequent and direct measures of student performance. Typically, goals are identified, a plan is developed, and then goals are evaluated at the end of the school year. The problem with this type of evaluation is that ineffective programs are not identified as ineffective until after they have been implemented for some time. The end result for students is that they have had a year of ineffective instruction, widening the gap between their performance and that of their peers. Alternatively, a combination of both formative and summative evaluation should be used to maximize decision making, described below.

FORMATIVE EVALUATION

Formative evaluation involves assessment during ongoing instruction. With a formative evaluation system, effective interventions identified during instruction are maintained, and ineffective interventions may be modified. From a system perspective, resources can be reallocated as needed based on progress toward the overall goal. For example, a school district may set a goal that all first graders will read 60 words per minute by the end of the school year. If data collected in January indicate that the median score is 10 words per minute, then a problem may exist and a program change needs to occur. In order for the goal of 60 words per minute in the spring to be met, students should be reading at least 20 words per minute in January. School psychology and other educational services in the district can be targeted to provide instructional and behavioral consultation to first-grade teachers and students in need of assistance to improve outcomes.

Information collected during the formative evaluation process also provides a mechanism to evaluate the contribution of the school psychologist in meeting the goals set by the education agency. A number of questions (See Table 1) may be asked when data collected during the formative evaluation process indicate that student progress is insufficient. Consideration of these questions will enable changes to be made in the overall service-delivery model as well as in individual student programs.

SUMMATIVE EVALUATION

While formative evaluation takes place during instruction, summative evaluation occurs, for example, at the end of the school year. Summative evaluation should occur at the end of each year to determine if the system goal has been met. If so, then it can be concluded that the service-delivery model was effective and the focus can shift to maintaining the current model and level of psychological services. If goals have not been met, then decisions will need to be made about the overall service-delivery model and the allocation of psychological and other educational services. Many of the questions asked during the formative evaluation process should be re-evaluated as well.

Case Study

To further illustrate how to evaluate psychoeducational services using student outcome data, a case study is presented using data collected from an elementary school in a Midwest state. The format of the case study will follow the "best practices" steps outlined above.

CLEARLY DEFINED GOALS

The school district determined that the basic skill area of reading was a top priority. Students in this state are

Table 1. Useful system-level questions to ask when student progress is insufficient

1. Is the percentage of time allocated to instructional and behavioral consultation sufficient?
2. Are teachers and principals supportive of the school psychologist's change in roles and responsibilities?
3. What are the perceived barriers preventing progress?
4. Are the resources of people, time, and materials flexibly assigned to meet student needs as they change over time?
5. Is more time for interventions or extra instruction available for students who are not meeting the goal?
6. Are curricular programs in place that are empirically validated to produce positive outcomes for students?
7. Is targeted staff development available for regular and special education personnel to acquire skills needed to implement "best practices" for students with learning and adjustment difficulties?

required to take a high-stakes basic skill reading test in grade 8. That is, in order to receive a high school diploma, students must earn a score of at least 80%. Since 1995, this particular district has conducted Benchmark Testing (Shinn, Shinn, Hamilton, & Clark, in press) for all students in the areas of reading, math, and written expression using CBM.

After examining the Benchmark data collected during the 1995–1996 school year, the district was concerned about student progress in the area of reading. Knowing that remediation of reading skills is very difficult, particularly when students reach middle school and above, the district decided to take a proactive approach and focus on improving beginning reading instruction for students in grades K–2 and general reading instruction for students in grades 3–5. The district set criterion scores at each grade level (established through research) that students would meet by the spring of each school year. These goals are summarized in Table 2.

The district believed that student reading performance was an applicable indicator for assessing the effectiveness of school psychology services for a number of reasons. First, it is well documented that when students achieve academic success in school, then other problematic social behaviors are less prevalent. Second, school psychologists can play a key role in working with both regular and special education teachers to improve reading instruction for students. For example, school psychologists can help teachers set ambitious goals for students to help increase their achievement, and they can assist in the design of interventions when progress is not satisfactory. Finally, the current trend in school psychology emphasizes the pivotal role that school psychologists can play in the areas of prevention and intervention to provide positive outcomes for all students. The district believed that using the school psychologist as an instructional consultant in the area of reading would promote their role in prevention and intervention.

DETERMINE PERFORMANCE INDICATORS

The district chose to measure student performance in the basic skill areas by using CBM. In the area of reading, students were given three reading passages from grade-level text and asked to read aloud for 1 minute. The district followed standard CBM administration and scoring methods (Shinn, 1989). The score that was used was the number of words read correctly (WRC) in 1 minute.

Table 2. Goals set by the St. Croix River Education District

Grade	*Goal*	*Performance indicator*
K	By spring of the school year, when presented with a random list of letters, students will name 40 sounds per minute.	Letter sounds/minute
	By spring of the school year, when presented with a word, students will be able to segment phonemes at a rate of 35 per minute.	Phonemic segments/minute
1	By spring of the school year, students will read at a rate of 55 words per minute from first grade level passages.	Words correct/minute
2	By spring of the school year, students will read at a rate of 80 words per minute from second grade level passages.	Words correct/minute
3	By spring of the school year, students will read at a rate of 90 words per minute from third-grade–level passages.	Words correct/minute
4	By spring of the school year, students will read at a rate of 110 words per minute from fourth-grade–level passages.	Words correct/minute
5	By spring of the school year, students will read at a rate of 120 words per minute from fifth-grade–level passages.	Words correct/minute
6	By spring of the school year, students will read at a rate of 135 words per minute from sixth-grade–level passages.	Words correct/minute

DESCRIBE THE RELATIONSHIP BETWEEN PSYCHOEDUCATIONAL SERVICES AND GOALS

The district determined that the most powerful academic services for the most students, using existing resources, would be provided through a flexible model of service delivery. This model included the following four key elements: (a) frequent and continuous measurement of all students, (b) grade-level team meetings, (c) concentrated resources, and (d) flexible grouping. The role of the school psychologist was restructured to include these elements, described in more detail below.

FREQUENT AND CONTINUOUS MEASUREMENT

Frequent and continuous measurement of student progress was the critical element in monitoring progress toward individual student goals and the overall system goal. Rather than wait until the end of the school year to determine if the goals were met, progress was monitored regularly so interventions could be implemented in response to student data. Benchmark Testing (Shinn et al., in press) was conducted with all students three times per year. The purpose of Benchmark Testing was to monitor the progress of each student regularly; to call immediate attention to students having difficulty; to aid communication between teacher, parents, and other professionals; and to provide information on effectiveness of educational programming. The school psychologist was responsible for facilitating the Benchmark Testing in collaboration with education district staff. Specific duties of the school psychologist included arranging (a) who would conduct the testing, (b) training for testers (initial and follow-up), (c) scheduling, (d) logistical issues such as where testing occurred and what equipment was needed, (e) materials for conducting testing, and (f) activities and timelines.

Strategic Monitoring (Shinn et al., in press) was conducted once per month on all students who were at-risk for reading failure so that changes in instruction could be made as soon as possible. More intensive monitoring was conducted weekly on all students receiving special education services or experiencing significant difficulties in reading. Frequent monitoring served several purposes. First, it provided a basis for evaluation of instructional programming for individual students with difficulties. Second, it provided information to help teachers make decisions about goals, materials, levels, and groups. Third., it documented progress for students on Individual Education Plans (IEP). The school psychologist was responsible for facilitating the strategic and intensive monitoring procedures. They helped by (a) identifying students who would benefit from either strategic or intensive monitoring, (b) identifying goals and monitoring level material (i.e., difficulty of material), and (c) organizing data collection procedures.

Collecting data on a regular basis was of no use if the data were not utilized. Thus, in each building, a system of data-review was established. School psychologists, along with other education district staff, provided training to teachers and support staff on graphing student progress (i.e., setting up graphs, establishing baselines, setting goals, drawing trend lines). The school psychologist was responsible for meeting with grade-level staff on a weekly basis to review student graphs. If individual or groups of students were not making progress, then the team reorganized instructional resources and designed interventions. The school psychologist was available to these teams as an instructional consultant. Thus, they observed in the classroom and made recommendations to teachers on how instruction could be modified for students.

GRADE-LEVEL TEAM MEETINGS

The principal arranged a common preparation time for teachers in each of the different grade levels. Grade-level teams met on a weekly basis to examine student graphs and make decisions about student progress. The school psychologist was assigned to attend grade-level meetings on a regular basis. If the school psychologist were unable to attend, then the grade-level team leader met with the school psychologist at an alternative time to discuss students of concern and review the team's decisions.

CONCENTRATED RESOURCES

Each grade level had reading instruction scheduled at the same time. Grade level teams were responsible for allocating instructional resources (i.e., paraprofessionals and volunteers) based on student need. The school psychologist was available to assist in decision making with respect to these instructional resources. All decisions were data-based, using the measurement system described earlier.

FLEXIBLE GROUPING

The elementary school organized itself to deliver three levels of reading remediation, aside from the typical reading curriculum that met the needs of students achieving at grade level. The first level involved within-class and within-curriculum interventions designed to provide the extra instruction needed to keep a student up with grade-level curriculum. The second level involved replacing the typical reading curriculum with the *Direct Instruction: Reading Mastery Curriculum* (Engelmann et al., 1995). The third level of remediation involved replacing the typical curriculum with the *Direct Instruction: Corrective Reading Curriculum* (Engelmann et al., 1999). All students were grouped according to skill level and moved in and out of the three levels using data to guide decisions. The school embraced the notion that students were not locked in to a specific group for the entire year. Students could move in and out of groups according to their rates of progress. The school psychologist was available to assist teachers in administering Direct Instruction Placement Tests, to determine appropriate grouping, and to assist grade-level teams in making decisions about changing levels of remediation.

FOCUS ON COLLABORATION AND TEAMWORK

Collaboration and teamwork was an integral factor in determining whether the school district would meet their goals. District staff realized that the public was demanding accountability from schools, particularly with the addition of high-stakes testing in the state. The principal created an atmosphere of collegiality and collaboration by obtaining input from staff on the overall service-delivery model for reading and how to concentrate resources in areas of need. The state operates under a categorical service-delivery model for serving students with special education needs. With the knowledge that many students experiencing significant learning problems do not qualify for special education, the challenge was to redesign the service-delivery model so that *all* students' needs could be met in the area of reading. The district realized that the resources of general education, compensatory education, and special education would need to be integrated to address the needs of students with learning problems. Furthermore, they realized that there would need to be increased flexibility in the use of special education support personnel. Special education teachers would not be limited to teaching only special education students. Nor would special education teachers always teach special education students. Students were assigned to instructional groups based on achievement levels, not by disability categories. Switching over to this type of service delivery philosophy *required* that teachers and support staff work as a team to meet the needs of students.

As was discussed earlier, grade-level teams were formed to review student data on a regular basis. These teams identified the instructional needs of students and allocated resources (paraprofessional and teaching staff) according to need. Therefore, some teachers received very little paraprofessional support while others received a great deal of support. The determining factor was ***student need***. The school psychologist helped foster collaboration and teamwork among the grade-level teams by continually redirecting the staff toward the identified goals and the subsequent needs of individual and groups of students.

EVALUATION OF PROGRESS TOWARD GOALS

To determine whether progress was being made toward the "system-level" goal, student progress was measured using both Benchmark-Testing and Strategic Monitoring (Shinn et al., in press). All students were assessed using Benchmark Testing, and Strategic Monitoring was used for students of concern. Each year, formative and summative data are analyzed, and changes are made to the service-delivery model when warranted. School psychology services are continually evaluated using these data and are targeted at grades where performance is of most concern. Without this information, the district would not be in a position to make decisions about individual students and the overall service-delivery model of psychoeducational services.

Figure 1 summarizes Benchmark Testing data from the 1996–1997 school year, the first year of the new service-delivery model. The target line is the goal that was set for each grade level. The data points represent the median performance of the students at each grade. With the exception of first grade, the median performance of each grade level was at the projected goal in the winter. Because the first grade scores were not lower than expected, interventions were implemented with all students who were below the Winter Goal of 20 WRC per minute.

Figure 1. 1996–1997 oral reading data by grade

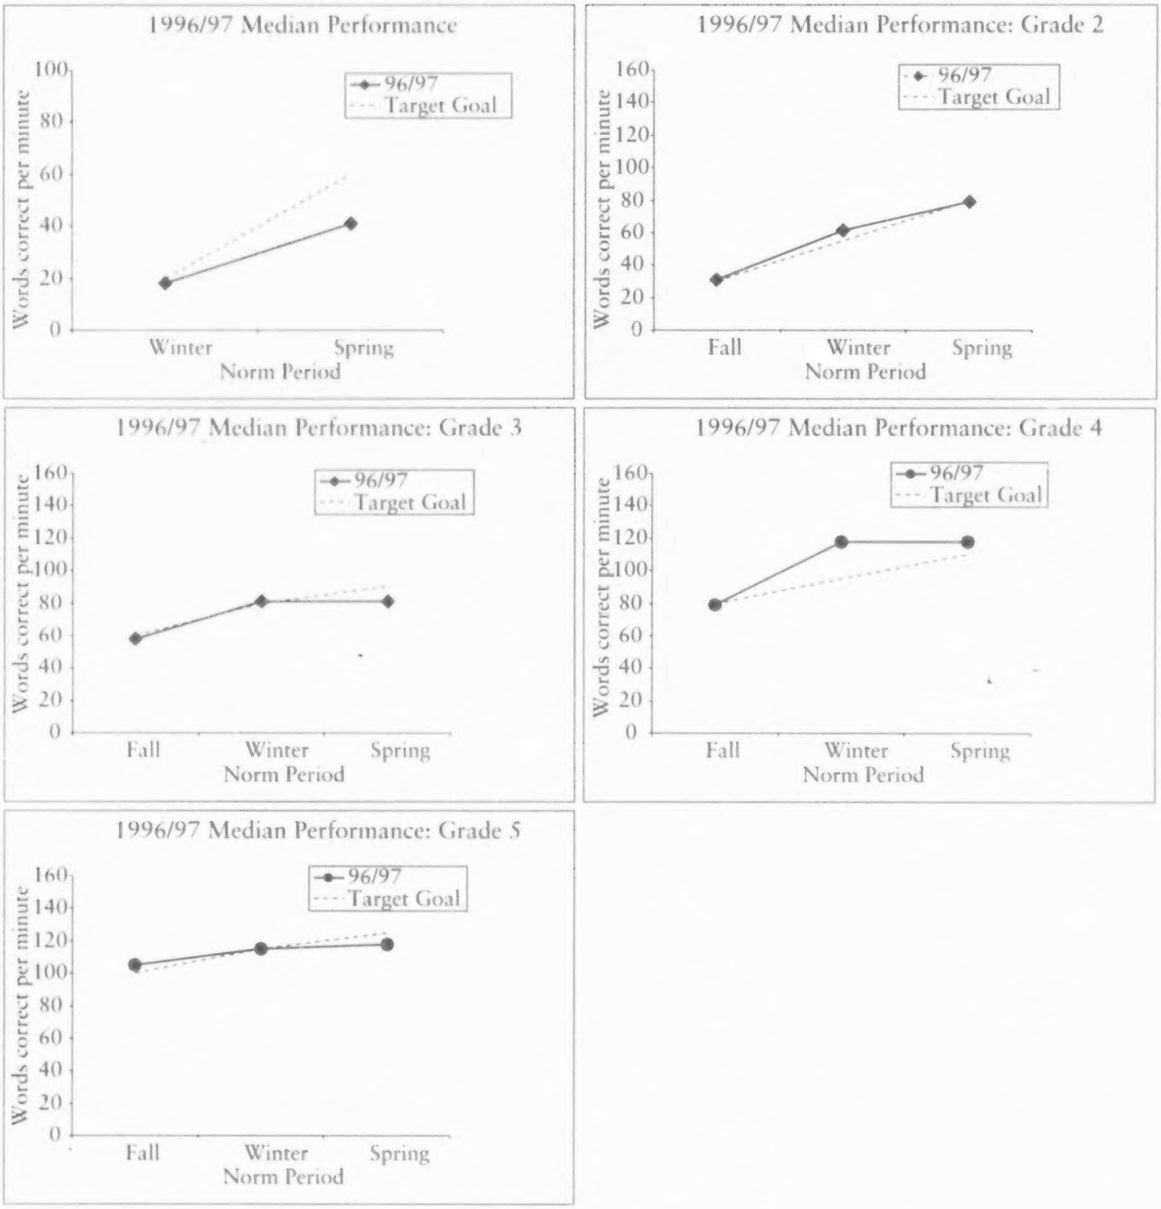

Figure 2 is an additional example of how Benchmark data were summarized and used to make decisions. This table displays the number of students who read at varying reading rates. As seen in Figure 2, 23 students read below the target goal in January. Of these students, none was receiving special education services, and four received Title One services. This information provided teams with a way to target services at specific students and assisted in making decisions about referring students for special education services.

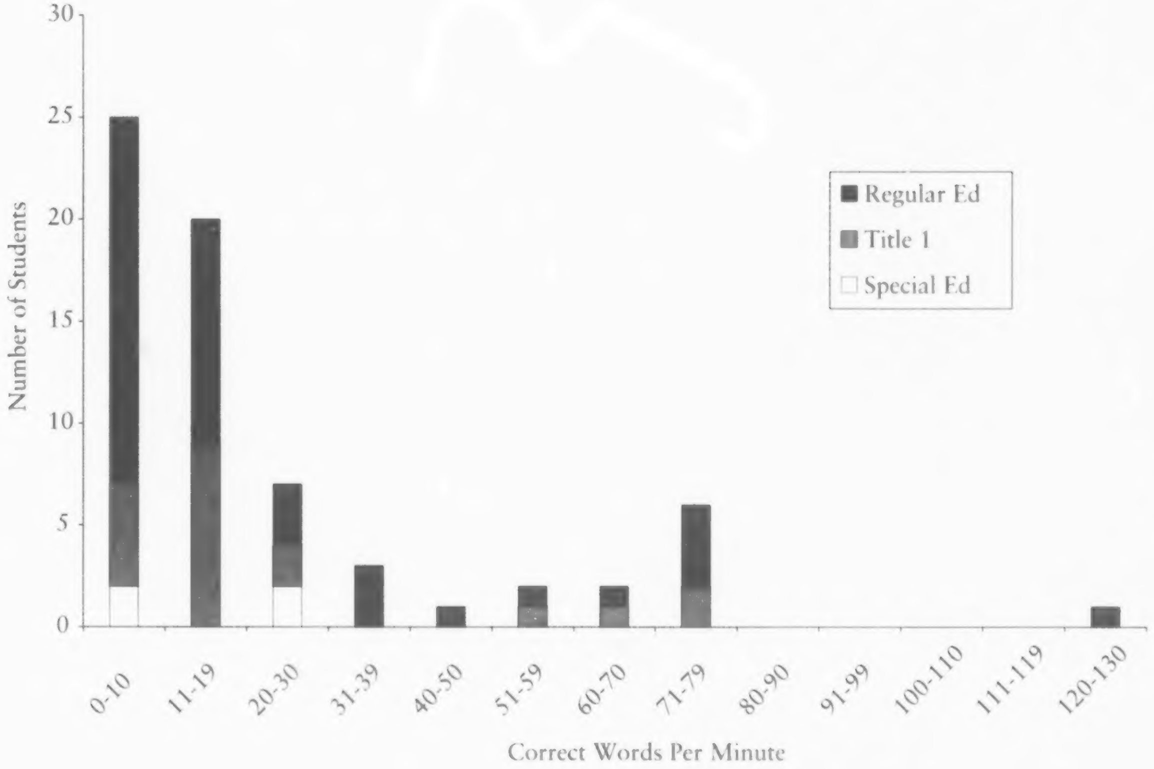
At the end of the 1996–1997 school year, the median score for all grades except for first grade was

Figure 2. Grade 1 oral reading data: Winter 1997



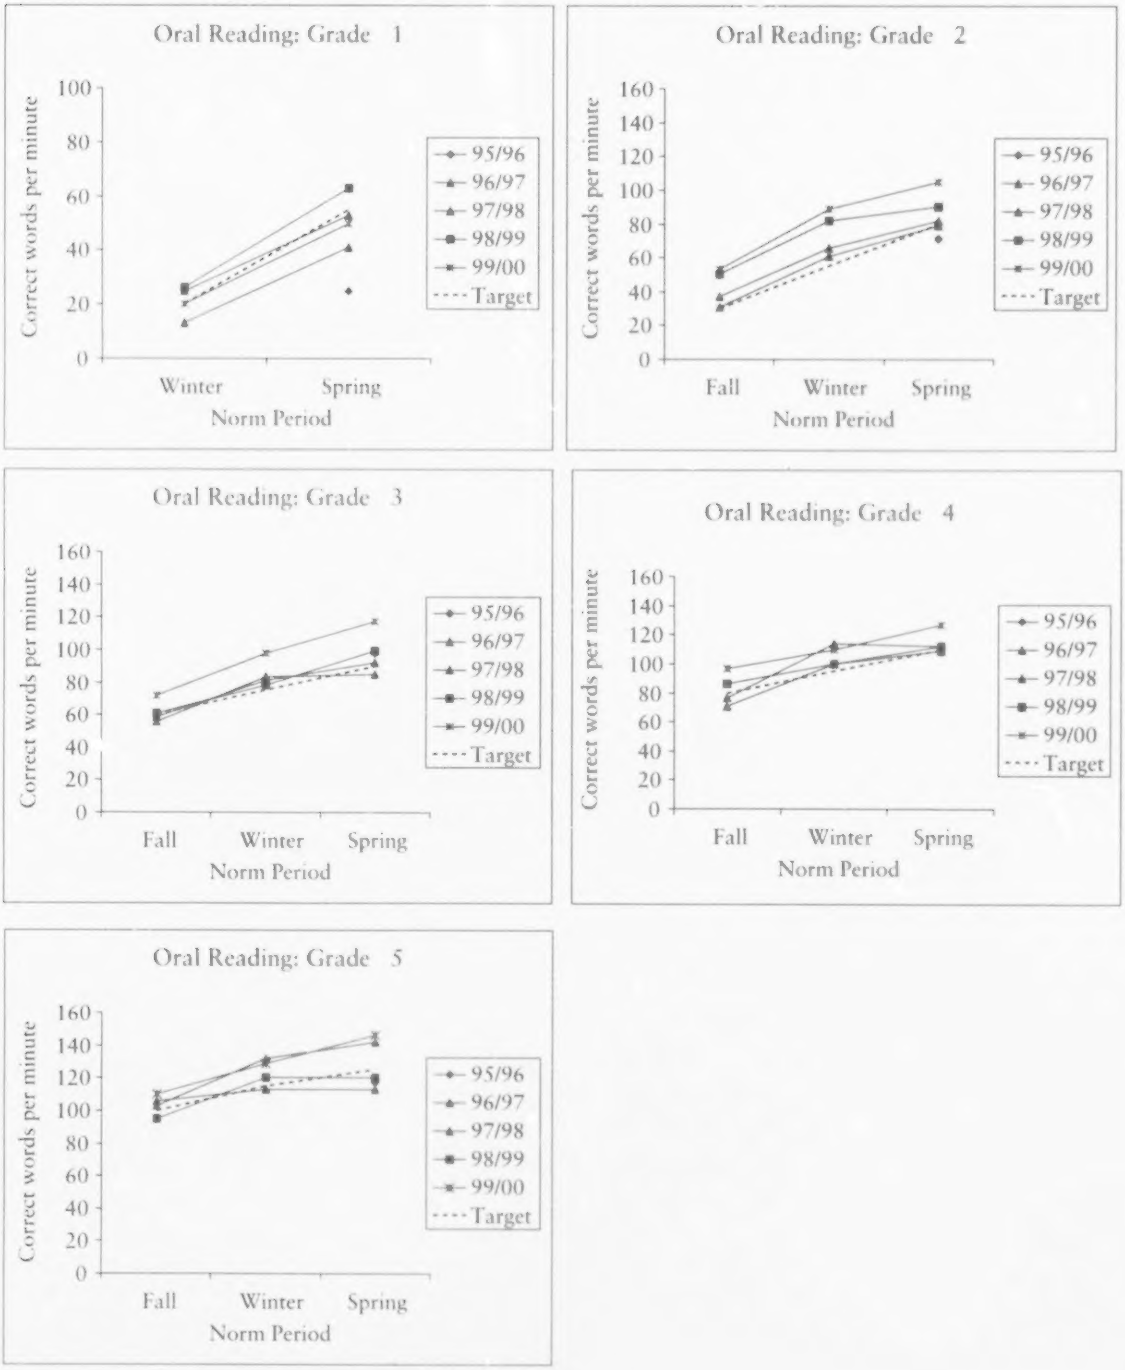
at the projected goal. Although significant progress had been made as compared to the previous school year, the district was not satisfied with the results for two reasons. First, even though the median performance for each grade level met the projected goal, 50% of students did not reach the goal. The district wanted *every* child to be reading at the projected target rate. Second, the scores for first grade were well below the target rate. A great deal of research conducted in beginning reading indicates a high correlation between poor reading performance at the end of first grade and poor reading performance in the later elementary grades. For example, Juel (1988), found the correlation between poor reading in first grade and poor reading in fourth grade to be .86.

The district wanted to intervene with beginning readers as quickly as possible to prevent future reading difficulties. For this reason, reading consultants were hired to work on incorporating the beginning reading research into the district's beginning reading instruction (grades K–2). School psychologists from the district attended this training and were instructed to incorporate the training into their instructional consultation. Figure 3 displays data collected through the 1999–2000 school year. As displayed on Figure 3, the median performance at all grade levels has increased significantly, with the median scores for each grade level surpassing the projected goal. Most important, very few students are reading below the target goal.

IMPLICATIONS FOR SCHOOL PSYCHOLOGY SERVICE DELIVERY

This case example establishes a system-wide reading goal and uses student reading data to evaluate school psychology and educational services. To some people, it may seem that evaluating school psychology services based on student achievement data is a stretch, especially if the role of the school psychologist is as consultant. However, school psychologists are increasingly being called upon to provide leadership

Figure 3. Oral reading data by grade: 1996–2000



to both regular and special educators in the design, delivery, and evaluation of instructional programs. A meaningful way to evaluate the effectiveness of their leadership is to examine student achievement data. In the previous case example, the school psychologist played a pivotal role in moving the educational team toward increasing student achievement in reading. The key facet was coordinating and implementing benchmark and strategic monitoring systems and consulting with the team to design *and* implement interventions when student progress was insufficient. Without regular progress data, the district would not have been in a position to intervene early with students of concern and make summative judgments regarding goal attainment.

Collecting this type of data has affected the role of the school psychologists in this particular district. There has been a dramatic decreasing in assessment for special education eligibility, in part, because many more student needs are able to be accommodated within the regular education environment. Owing to the decrease in formal testing, the school psychologists are able to devote much more time to instructional and behavioral consultation. On a yearly basis, decisions are made about the amount of school psychology support that should be provided to particular grade levels. For example, in the previous case study, the school psychologist was directed to spend more time consulting with first grade staff during the 1997–1998 school year in response to the outcome data. How much impact school psychology services had on student achievement certainly is open to debate. However, the critical factor is not necessarily the amount of impact the school psychologist had on student reading achievement, but the fact that presently very few students are reading below the district's target goal.

SUMMARY

Schools are becoming increasingly more accountable for student outcomes. This accountability movement *necessitates* the use of student outcome data to evaluate the effectiveness of the services provided by school psychologists and other educational service providers. The educational research literature contains numerous references to results; however, results have rarely been operationalized. By using valid and reliable student outcome data is one way to operationalize educational results.

This chapter focused on how school psychoeducational services may be evaluated using student outcome data. Critical variables in this process include clearly defined goals, direct performance indicators of student achievement, a relationship between psychoeducational services and goals, a focus on collaboration and teamwork, and formative and summative evaluation of progress toward goals. All of these variables operate interdependently to produce results. Concentrating on results does not negate the importance of process (i.e., a good service-delivery model). Rather, results tell us whether the process is effective and to what extent the process needs to be reexamined and adjusted. Regular monitoring, followed by adjustment, is the only way to expect success.

This article describes the development of a data-based service-delivery model for school psychologists practicing in the Minneapolis Public Schools. Methods used to evaluate the effectiveness of school psychological services are described, including the use of time analyses and tabulation for program evaluation and the use of Reading Curriculum-Based Measures to evaluate student outcomes.

Fairchild, T. N., and Zins, J. E. (1992). Accountability practices of school psychologists: A 1991 national survey. *School Psychology Review, 21*, 617–627.
This article details the results of a 1991 survey of the accountability practices of school psychologists. The survey is a follow up to a 1984 study by the same authors. Results from both studies were compared for differences. However, the authors found no significant differences in reported accountability practices between the 1984 and the 1991 surveys. Implications for practice are discussed.

Fuchs, L. S., & Fuchs, D. (1999). Monitoring student progress toward the development of reading competence: A review of three forms of classroom-based assessment. *School Psychology Review, 28*, 659–671.

This article describes and critiques three methods for monitoring student progress toward competent reading: Mastery Measurement, CBM, and Dynamic Indicators of Basic Early Literacy Skills. The authors discuss six considerations in selecting monitoring systems that produce meaningful information about students. Next, the three methods are critiqued against the six considerations. Finally, the authors discuss areas of future research to provide school-based practitioners with a meaningful monitoring system.

Schmoker, M. (1996). *Results: The key to continuous school improvement.* Alexandria, VA: Association for Supervision and Curriculum Development.

In this book, the author examines the conditions and theory behind obtaining dramatic results in school-based settings. The foundation for results, as presented by Schmoker, is meaningful teamwork combined with setting clear, measurable goals and regularly collecting and analyzing performance data. The author emphasizes the importance of principles and practices that are simple, supported by research, and relatively few in number.

Best Practices in Preventing and Managing Stress and Burnout

E. Scott Huebner
University of South Carolina
Tammy Dew Gilligan and Harriet Cobb
James Madison University

OVERVIEW

The purpose of this chapter is to discuss sources and management of occupational stress among school psychologists. First, the nature and correlates of school psychologists' stress and burnout reactions are delineated. Both individual and organizational factors are addressed. Second, strategies to prevent job stress and promote emotional resilience are provided. Although a model of well-being is presented that incorporates environmental as well as personal variables, the authors believe that school psychologists can exert influence over their professional destinies, provided that they proactively attend to their own needs as well as those of their clients.

For many years, studies of occupational stress and burnout have been prominent in the organizational psychology literature. Nevertheless, only a handful of studies of stress and burnout has been reported in the school psychology literature. Given that many school psychologists are interested in expanding their direct and indirect intervention-related service activities, it is surprising that school psychology researchers and practitioners have shown little attention to the affective reactions of the service deliverer (i.e., the school psychologist). Knowledge of counselors' affective states has long been considered central to a complete understanding of counseling processes and outcomes (Corey, 1996). The emotional well-being of counselors and other related professionals, such as school psychologists, may facilitate or impede effective service delivery. For example, an optimistic, emotionally resilient school psychologist may interact very differently with clients than a pessimistic, emotionally stressed school psychologist.

School psychologists have undertaken extensive explorations of numerous aspects of intervention-related services, such as consultation with teachers and parents. Although studies have investigated a variety of parameters of the consulting relationship (e.g., consultee characteristics, consultation process variables, intervention integrity), few studies have directly explored the affective and motivational characteristics of the consultant. Such neglect could undermine school psychologists' efforts to implement, evaluate, and understand the effectiveness of their services. Similarly, such neglect could also impede their efforts to develop systematic change strategies to promote emotional resilience and/or improve their work environments.

Occupational stress and well-being have been recognized by some authors as important areas of concern among people-oriented service professionals, including school psychologists (e.g., Huebner, 1992; Wise, 1985). Among psychologists, occupational stress has been operationalized and studied mostly through the use of occupational burnout measures. Initially defined in relation to crisis workers (Freudenberger, 1974), the burnout concept as been elaborated upon by various researchers, most notably by Christina Maslach and her colleagues (e.g., Maslach & Goldberg, 1998). In its broadest terms, the concept relates to affective responses by professionals to the chronic stresses of working in a professional relationship with others in need. More specifically, Maslach argues that burnout is multidimensional, composed of three related, but differentiable, constructs: emotional exhaustion, depersonalization, and reduced personal accomplishment. Emotional exhaustion relates to feelings of being emotionally overwhelmed by the demands of the job. Individuals experiencing emotional exhaustion feel emotionally depleted and often reduce their involvement with others, including clients and co-workers. Depersonalization is experienced through negative, detached responses to clients. For example, school psychologists may develop cynical attitudes toward some consultees and/or clients and "blame the victims" for their difficulties. Reduced personal accomplishment refers to feelings of decreased professional competence. For example, school psychologists may develop feelings of helplessness with respect to their ability to make a difference and to assist those in need. Current research suggests a developmental model of burnout, in which emotional exhaustion occurs initially, followed by depersonalization responses, while reduced professional efficacy occurs separately (Maslach & Goldberg, 1998). Taken together, these burnout dimensions reflect a developmental transition from a positive problem-solving approach toward job responsibilities to a negative, avoidant approach. Such a transition is consistent with Freudenberger's (1974) notion that burnout-prone individuals begin their careers as highly motivated, idealistic, and caring.

The consequences of burnout can be varied. Burnout reactions have been related to physical problems, psychological disorders, drug and alcohol abuse, and interpersonal difficulties, at home and on the job (Maslach & Goldberg, 1998). Furthermore, burnout has been shown to predict the experience of subsequent occupational stressors (Mills & Huebner, 1998). Although some psychologists may leave the profession, others may remain, but operate at a level of reduced productivity. Such outcomes are particularly tragic for professionals who begin their careers with high levels of motivation, skill, and enthusiasm. Whatever the case, such outcomes negatively impact the many consumers of school psychological services, which include individuals (e.g., child, teacher), groups (e.g., parent groups), and organizations (e.g., school districts, community agencies).

A few studies of the prevalence of burnout among school psychologists have been conducted. In the most recently reported national (U.S.) survey of practicing school psychologists, Huebner (1993) found that more than 25% of the respondents reported high emotional exhaustion, 3% reported high depersonalization, and 12% reported a reduced perception of professional accomplishment. A total of 35% of the sample reported some level of desire to leave the profession within the next 5 years. Compared to a sample of consulting psychologists, school psychologists reported higher levels of emotional exhaustion and depersonalization as well as lower levels of professional accomplishment. Compared to a sample of clinical/counseling psychologists, the school psychologists reported equivalent emotional exhaustion, lower levels of depersonalization, and lower levels of personal accomplishment. Thus, school psychologists may be at greater risk for various forms of burnout than other psychological service providers.

BASIC CONSIDERATIONS

Recent models of burnout incorporate personal and contextual variables. In these models, stress and burnout reactions develop as the result of the interactions between individual difference variables (e.g., demographic characteristics, personality factors, skills and training differences) and environmental variables (e.g., organizational and interpersonal variables). In other words, burnout is conceptualized as a mismatch between the person-job fit. In these models, attention is thus directed toward both personal and situational sources of stress and burnout. In our model, burnout is conceptualized as a function of risk/resiliency factors. Borrowing from the current paradigm in developmental psychopathology, risk factors for problems interact with individual strengths and vulnerabilities to predict the degree of resilience an individual possesses (Cicchetti & Garmezy, 1993). Protective mechanisms in the environment may serve to mediate risks and vulnerabilities to produce wellness and some "immunity" to burnout. For school psychologists, an analysis of the risk factors, personal strengths and vulnerabilities, and protective mechanisms may help in the understanding and prevention of the process of burnout.

Personal Risk/Resiliency Factors

Personal risk factors include demographic variables and personality characteristics (both strengths and vulnerabilities). The variables of school psychologists' age and years of experience have been the only demographic variables to demonstrate robust relationships with burnout. Younger, less experienced school psychologists are more likely to report emotional exhaustion, depersonalization, and reduced professional accomplishment (Huebner, 1993). School psychologists' age level has also been linked with the experience of job-related stressors, such as interpersonal conflict and time management difficulties (Huebner & Mills, 1997), again with younger school psychologists more likely to experience stressors.

Personality factors have also been associated with burnout reactions. Introversion and disagreeableness both relate to feelings of emotional exhaustion. In addition, introversion relates to reduced professional efficacy, and disagreeableness relates to depersonalization (Mills & Huebner, 1998). Sandoval (1993) found that persons who reported overall low self-esteem, narrow interests, and difficulty coping with ambiguity were more likely to report burnout reactions. Conversely, extraversion, flexibility, and optimism were personal characteristics associated with strength and resilience.

Organizational Risk Factors

The school psychology literature has identified organizational factors, specifically job stressors, that are quite deleterious. Wise (1985) reported the following nine stressful factors:

1. Interpersonal conflict (interactions with resistant teachers or uncooperative administrators)

2. High risk to self and others (dangerous or crisis situations, due process hearings, child abuse cases, teachers' strikes)

3. Obstacles to efficient job performance (inflexible and/or incompetent supervisors, inadequate secretarial help, feeling caught between the child's needs and administrative constraints, lack of contact with professional colleagues)

4. Public speaking (inservice workshops, public speaking engagements, parent groups)

5. Time management (backlog of reports or referrals, "feeling behind")

6. Legal mandates (due process, compliance with regulation issues)

7. Hassles (carrying materials between schools in bad weather, driving)

8. Professional enrichment (difficulty keeping up with the literature in the field)

9. Insufficient recognition of work ("not enough strokes")

Additionally, other organizational factors are risks. They include:

1. Role conflict

2. Role ambiguity

3. Role overload

4. The "fit" between the person and the job

Role conflict is a crucial organizational variable in burnout reactions (Pierson-Hubeny & Archambault, 1987; Wright & Thomas, 1982). Role conflict occurs when two or more conflicting job demands impinge on school psychologists in their delivery of psychological services. For example, role conflict may occur when school psychologists advocate for particular services for a child with special needs (e.g., inclusion) in the face of opposition from others, such as a principal who wants a child excluded from the regular classroom environment.

Role ambiguity is also a crucial variable in the development of burnout (Huberty & Huebner, 1988). Role ambiguity refers to a lack of clarity concerning the school psychologists' roles and responsibilities, privileges, status, objectives, etc. For example, school psychologists continue to debate their most important roles and functions—now and for the future—in the face of severe short- and long-term shortages of practitioners and trainers. This lack of agreed upon identity may be confusing to consumers, thus serving as a continuing source of frustration for school psychologists who seek to increase the perceived value of their services.

Role overload has also been implicated in burnout (Huberty & Huebner, 1988). Role overload can relate to quantitative or qualitative overload. Quantitative overload is defined as too many job demands relative to the amount of time available to meet them. Qualitative overload involves task complexity; that is, tasks that are difficult to complete effectively. Both quantitative and qualitative overload are interrelated with the quality and quantity of organizational resources available to school psychologists (Huebner, 1993). Examples of stressors related to qualitative overload among school psychologists include dealing with child abuse cases, suicide cases, working with difficult parents or teachers, and a lack of appropriate services for children (Huebner & Mills, 1997). Examples of quantitative overload for school psychologists include high student-to-school psychologist ratios (Huebner & Mills, 1994), heavy report writing responsibilities, pressure to complete a prescribed number of cases, and keeping up with the professional literature (Huebner & Mills, 1997; Wise, 1985).

Interestingly, in one study of quantitative overload, school psychologists' actual caseloads did not predict burnout responses whereas the discrepancy between their actual and ideal caseloads did predict burnout (Huebner & Mills, 1994). Such a finding underscores the notion that although contextual factors are important in occupational adaptation, it is the "fit" between the person and the job that must be understood.

Roles and Functions

Studies of the relationships among the frequency levels of various job functions and burnout have also supported the role of organizational factors. In one study, the number of hours spent in assessment-related activities correlated negatively with a sense of professional accomplishment, whereas the number of hours spent in intervention-related activities correlated positively with a sense of professional accomplishment (Huberty & Huebner, 1988). In another study, the perceived importance of consultation and counseling activities, but not assessment activities, correlated significantly with professional accomplishment. Nevertheless, the perceived importance of assessment activities was related significantly to emotional exhaustion and depersonalization reactions (Huebner, 1993). The latter findings suggest that changes in roles and functions must be considered carefully because they relate differentially to burnout dimensions. For some school psychologists, it is thus possible that increases in intervention activities along with a concomitant decrease in assessment activities could increase self-perceived professional accomplishment while also increasing the potential for emotional exhaustion or depersonalization reactions. For other school psychologists, increases in assessment-related activities could lead to decreases in emotional exhaustion along with increases in boredom or frustration. Such reactions may be associated with the relative frequency with which school psychologists encounter occupational "flow states" (Csikszentmihalyi, 1990) in which the level of job difficulty is optimally matched to their skills, with tasks being neither too easy (leading to boredom) nor too difficult (leading to anxiety and frustration).

Analysis of these multiple factors that relate to school psychologists' well-being can help elucidate individual's risk of burnout. Consider three individual school psychologists with differing risks, strengths and vulnerabilities, and protective mechanisms (see Figure 1). Alice is a generally optimistic person (strength) who has a tendency to be somewhat anxious (vulnerability). Job expectations have felt overwhelming at times, and indeed her testing load for special education eligibility is excessive (organizational risk factor). However, she has a supportive supervisor who serves as a buffer between Alice and some inflexible administrators (organizational protective mechanism). When Alice initiated a focused discussion with her supervisor about role overload, she received emotional support and suggestions for renegotiating her caseload with one particular principal. Generally, aside from some anxiety during the last 2 months of the school year, Alice's overall sense of well-being is strong. She is at low risk for burnout.

Mark, on the other hand, has two organizational risk factors: an excessive workload and an ineffective supervisor. Furthermore, while his organizational and time management skills are good (strength), he is somewhat pessimistic (vulnerability). His family is emotionally supportive (organizational protective mechanism), however, and after participating in indi-

Figure 1. Resiliency/Burnout Model for School Psychologists

Risk factors	*Personal characteristics (Strengths/vulnerabilities)*		*Protective mechanisms*	*Risk for burnout*
(Alice) Role overload	Optimistic tendencies	Predisposition to anxiety	Good supervisor	Low
(Mark) Role overload and ineffective supervisor	Good organizational and time management skills	Pessimistic tendencies	Personal counseling and supportive family	Mild to moderate
(Susan) Role overload and ineffective supervisor and divorce	Extraversion	Limited experience as a school psychologist	None	High

vidual therapy (protective mechanism), Mark moved from being at high risk to only mild risk for burnout.

Susan is at great risk for burnout. Not only does she have role overload and an ineffective supervisor (organizational risk factors), she is caring for an aging parent (personal risk factor). While she characterizes herself as an extravert (strength), she has only been a school psychologist for 2 years (vulnerability), and is experiencing isolation both on the job and at home (risk factor). Without significant intervention, she is at risk for depression and burnout. Intervention may need to include personal counseling as well as a major job change.

BEST PRACTICES

Preventing or mediating stress and burnout among school psychologists may be considered a dynamic process, with strategies in place to promote protective mechanisms at the intrapersonal, interpersonal, and organizational levels within both pre-service and inservice environments. The common goal of these strategies is to increase resiliency in school psychologists at the individual and systemic level. The following approaches should be considered as trainers, supervisors, and practicing school psychologists strive for optimal well-being and functioning on the continuum of professional burnout.

Pre-service Environment

Strategies for preventing and mediating stress and burnout at the pre-service training level include both student and training program responsibilities. A combination of these approaches can effectively serve as protective mechanisms and thus increase student resiliency at an early stage of their professional development.

PROTECTIVE MECHANISMS OF EFFECTIVE TRAINING PROGRAMS

Effective job skills mitigate job stress. Inadequate pre-service training in technical skills or social-emotional competencies can be risk factors for burnout. For example, school psychologists' ratings of their self-perceived competence in providing consultation services have been related significantly to all three burnout dimensions (Huebner, 1993). As school psychologists move to more diversified roles (e.g., crisis counseling, mental health consultant), appropriateness of pre-service preparation will likely become increasingly related to school psychologists' experience of stress.

Training programs should strive to provide a milieu that emphasizes academic/skills training *and* interpersonal and intrapersonal growth. This emphasis can begin with a program philosophy that recognizes the value in personal growth. Programs also should attempt to establish screening procedures of student applicants that consider intrapersonal and interpersonal characteristics to ensure a goodness of fit between the student, program, and profession. One such procedure is the use of group interaction interviews. This type of screening procedure allows for an on the spot picture of an applicant's flexibility, tolerance for ambiguity, and agreeableness. As was mentioned previously, research indicates that specific personality factors are associated with burnout reactions. Training programs' consideration of potential students' extraversion/introversion, disagreeableness, self-esteem, range of interests, and coping strengths (optimism and tolerance for ambiguity) could increase the likelihood that future school psychologists will be less vulnerable to stress and burnout.

Faculty members play a crucial role in establishing a pre-service environment that prepares students to mitigate job stress and professional burnout. Faculty modeling of self-care, well-functioning, stress management, and personal growth is a necessary component of student well-being and preparation. Faculty can also assist by embedding learning activities within the curriculum that promote intrapersonal and interpersonal development. These might include reflective writing, experiential activities, opportunities for teamwork, and frequent self-assessments. Training programs should consider stress management and stress inoculation seminars or workshops as a regular aspect of their program. Programs can reduce the likelihood of stress overload by fostering an atmosphere of cooperation rather than competition among students. A clear emphasis in the training milieu and curriculum on personal growth leads to frequent faculty evaluation of students' progress and areas of strengths and weaknesses. Thus, faculty should be prepared and willing to make developmental or preventative recommendations (e.g., participation in group or personal therapy) as well as remedial intervention suggestions. Faculty should also require students to join professional associations and attend professional conferences early in their training. This emphasis on professional networking and continuing education hopefully initiates an unswerving appreciation for peer support and life-long learning.

What follows provides a summary of protective components of effective training programs:

1. Up-to-date training
2. Program philosophy that emphasizes personal growth
3. Effective screening procedures to ensure goodness of fit with training program
4. Faculty modeling of self-care, well functioning, and stress management
5. Curriculum that promotes intrapersonal and interpersonal development
6. Provision of remedial interventions for students having difficulty
7. Atmosphere of cooperation and support
8. Requirements for student involvement in professional associations

RESPONSIBILITIES OF STUDENTS

Students also assume responsibility in the pre-service environment for the development of effective stress management strategies and the prevention or mediation of burnout. Most important, school psychology students should possess a general openness, flexibility, and willingness to explore and develop intrapersonal and interpersonal characteristics. Students must be active participants in program components such as:

1. Peer mentoring
2. Stress management training
3. Conflict management training
4. Professional process groups
5. Other self-awareness activities

Students must be willing to hear, accept, and follow feedback and recommendations for personal development including developmental or remedial intervention suggestions for personal or group therapy. One example of the importance of the student's role in mediating stress involved a second-year school psychology practicum student. This student felt that a faculty member did not fully appreciate her personal circumstances that were interfering with the completion of practicum assignments. Although the student became increasingly upset and withdrawn from the faculty member, she did discuss her concerns during a regularly scheduled process group meeting. As a result of feedback and encouragement from the process group, the student came forward to the faculty member in an emotionally mature manner to discuss her concerns. This led to mutual understanding and a successful resolution of the problem.

Inservice Environment

As with the pre-service environment, approaches to preventing and mediating stress and burnout are the responsibility of both the individual school psychologist and the system or organization. Combinations of protective mechanisms provided by the individual and the system's infrastructure can enhance resiliency of the professional school psychologist.

PROTECTIVE COMPONENTS OF EFFECTIVE ORGANIZATIONS

Continuing professional development is essential for the well-being of school psychologists. As Brown (this volume) states, new technologies, new information, and changing expectations mandate school psychologists' life-long learning activities. Participating in NASP's CPD programs should contribute to a sense of competency and satisfaction on the job.

Practicing school psychologists benefit from supervision and formalized peer support. Social support, especially from supervisors, is inversely related to depersonalization reactions of school psychologists (Huebner, 1994). Effective supervision can provide technical guidance, organizational integration, and nurturance (Russell et al., 1987). Supervision should involve a balance of task-oriented problem solving within the context of a positive work relationship. Recognition of the importance of supervisory support, particularly from supervisors who have been psychologists themselves, is crucial given the documented inadequacies of supervision experiences in school psychology (Zins, Murphy, & Wess, 1989). Such issues may be particularly important for practitioners in rural settings, many of whom report the lack of appropriate supervision services (Jacob-Timm, 1995).

Support from peers and other related professionals also helps to prevent burnout. Isolation from colleagues reduces opportunities for various types of support (Last & Silberman, 1989), which can be only partially provided by supervisors who are in a position of formal authority. For example, formal and informal interactions with peers can involve supportive functions, such as receptive listening, affirmation of competencies, technical information, emotional support, psychological insight, and "social reality" sharing (Pines, 1982). Professional peer support groups, such as those described by Zins et al. (1989) are particularly important given psychologists' reluctance to seek professional treatment for themselves since "helpers should need no help" (Millon, Millon, & Antoni, 1986). Systematic, individualized mentoring programs, in which new professionals are teamed with seasoned veterans, are also likely to be beneficial. The organizational infrastructure must encourage effective supervisory and collegial interactions to prevent and/or manage burnout.

As was previously discussed, burnout reactions have been connected to role conflict (i.e., two or more conflicting job demands impinge on service delivery), role ambiguity (i.e., lack of clarity concerning roles and responsibilities), and role overload (i.e., quantitative or qualitative complexity and demand). Organizations employing school psychologists should work toward reduction or elimination of these factors. Psychologists themselves can play an important role in facilitating a positive organizational structure for psychological services delivery. For lone school psychologists, good negotiating skills are essential.

In summary, organizational approaches that enhance the professional's resiliency to stress and burnout include the following:

1. Good supervision opportunities

2. Formalized peer support groups

3. Minimal role conflict

4. Clear delineation of roles and responsibilities

5. Avoidance of role overload

RESPONSIBILITIES OF THE PROFESSIONAL SCHOOL PSYCHOLOGIST

The practicing school psychologist also assumes personal responsibility for preventing and mediating burnout. As with students in training, the professional school psychologist should possess a general openness and willingness to evaluate levels of stress and burnout and explore intrapersonal and interpersonal characteristics that may contribute to this process. An initial step is to conduct a personal assessment of stress and burnout and develop an individualized stress intervention plan (Huebner, 1993) or an individualized effectiveness plan (Thomas, 1995). School psychologists must take the reflective time necessary, however, to envision an individualized stress management plan. This may mean visiting a favorite quiet spot and contemplating what strategies or changes must occur or lunching with a colleague to provide mutual support for this activity.

One organizational professional approach is for school psychologists to seek out and fully participate in supervision opportunities and peer-support groups. School psychologists should also maintain their membership and participation in professional associations because these provide valuable protective networking opportunities and support of the professional identity. In a similar fashion, school psychologists should engage in meaningful professional development activities throughout their career.

Studies of relationships among the frequency levels of various job functions and burnout have also supported the role of organizational factors. Thus, it may be necessary for school psychologists to modify or change their daily work schedules to allow for breaks and spacing of desirable versus less desirable professional activities

The professional school psychologist should also attempt to maintain a personal physical and mental health self-care plan. An appropriate balance of exercise, proper nutrition, and regular medical examinations is critical to this self-care plan. Individuals must also be willing to seek out appropriate physical and mental health interventions as needed.

The ability to maintain a high level of wellness over the course of a career was reflected upon by experienced school psychologists in a recent study by Guest (2000). A number of school-based practitioners in her study reported enhanced awareness and skills in self-care through a greater separation of their personal and professional lives. Such experiences included an "increased ability to set boundaries on how much they could do, greater ability to say 'no,' and increased ability to set priorities that reflected what they could realistically accomplish" (Guest, 2000, p. 250).

Other individual responsibilities for preventing and mediating stress and burnout include the use of cognitive reframing and maintaining a sense of humor and perspective throughout the work day (Thomas, 1995). School psychologists must remember the important role of optimism in contributing to an overall sense of well-being. If optimism is elusive, then help or change is needed. Optimism can be learned at any point in time, as was noted in the positive psychology movement (Seligman & Csikszentmihalyi, 2000).

The professional's responsibilities for tasks to mediating stress and burnout are summarized below:

1. Openness and willingness to self-evaluate current levels of stress and burnout

2. Commitment to design a personalized stress management plan

3. Participation in supervision and peer-support groups

4. Participation in professional associations and professional development

5. Changing the daily rut of job functions and roles

6. Partnering with other school personnel to try new activities

7. Maintaining a personal and mental health self-care plan

8. Maintaining a sense of optimism and humor

SUMMARY

Burnout refers to the negative consequences of chronic job stress. It is composed of the affective experiences of emotional exhaustion, depersonalization, and a reduced sense of personal accomplishment. School psychologists are vulnerable to professional burnout and, according to research, may be at greater risk than other helping professionals. Risk factors for burnout (e.g., role overload) interact with individual strengths (e.g., optimism) and vulnerabilities (e.g., introversion) to predict the degree of resilience an individual possesses. Protective mechanisms in the environment, such as appropriate supervision and peer support, may mediate these risks.

Training programs have an obligation to select applicants who possess characteristics that are associated with the development of resilience. Training programs must then foster resiliency through a philosophy that promotes self-awareness, personal growth, and skill development. Graduates from "resiliency-building" programs have a responsibility to choose positions that offer a reasonable probability of job satisfaction (e.g., quality supervision, atmosphere of support, realistic role expectations, and continuing professional development). Furthermore, it behooves school psychologists to continue throughout their careers to develop personal resiliency and to advocate for protective mechanisms within their organizations. Maslach and Leiter (1997) articulate an excellent model to guide professionals, such as school psychologists, in the implementation of organizational change efforts to promote enhanced person-job fit.

ANNOTATED BIBLIOGRAPHY

Cherniss, C. (1995). *Beyond burnout: Helping teachers, nurses, therapists, and lawyers recover from stress and disillusionment*. New York: Routledge.

In contrast to the more typical stress-related models of burnout, Cherniss discusses burnout from the perspective of a professional's varying nature and level of ideological commitment and moral purpose related to her or his career. This book is of particular relevance to school psychologists and includes an informative case study of one school psychologist's successful efforts at changing his role and function.

Maslach, C. (1982). *Burnout: The cost of caring*. Englewood Cliffs, NJ: Prentice-Hall.

The reader should not be misled by the date of this text. It is one of the classics in the field. Maslach's book remains full of useful individual, group, and organizational change ideas to assist human services professionals in the prevention and/or management of occupational stress and burnout.

Maslach, C., & Leiter, M. (1997). *The truth about burnout*. San Francisco: Jossey-Bass.

This book is authored by two of the foremost researchers in the area of burnout and provides an excellent discussion of two problem-solving approaches (individual and organizational) to modifying person-job linkages to prevent job burnout and promote job engagement. Realistic case studies are included to illustrate the change process.

13 Best Practices in Professional Development

Michael Brown
East Carolina University

OVERVIEW

The completion of a graduate training program in school psychology provides the initial base of knowledge and skills for professional practice. Innovative technologies, changing expectations, and new information require school psychologists to continue learning throughout their careers. The purpose of this chapter is to provide a basis for school psychologists in developing and implementing effective continuing professional development plans for themselves and for psychologists they may supervise. After reviewing the history and present status of continuing professional development (CPD) in school psychology, a four-step model is presented for planning and implementing CPD activities. Two examples of integrating individual CPD activities with staff development activities are described that will encourage school psychologists to broaden their perspective on the role of CPD in effective professional practice.

One of the hallmarks of a profession is that it has a recognized body of specialized knowledge. Implied in this definition is the responsibility of the profession to educate its members at initial entry into the profession and as a continuing professional responsibility (Young, 1987). Incumbent upon a professional is the obligation to continuously improve one's knowledge and skills by becoming a lifelong learner (Houle, 1980). Role expansion and educational reform have placed increased demands on school psychologists' knowledge and skills, increasing the need for continuing professional development (Reiher & Triggs, 1995).

While individuals have always continued to learn through reading, discussions with colleagues, and through practical experience, the later half of the twentieth century has been marked by a move toward formal continuing professional education (Cervero, 1988). Continuing education has emerged as a primary purpose of many professional organizations (Schrank & Young, 1987), and most professional organizations encourage or require formal continuing education. Both the National Association of School Psychologists (NASP) and the American Psychological Association (APA) recognize the importance of CPD in their codes of ethics, and both have established formal programs to encourage their members to continue to develop and refine their work-related knowledge and skills.

NASP began a voluntary CPD program in 1975 (Walker, 1977). The program recognized three broad areas of competence in school psychology (assessment, intervention, and program development) and required school psychologists to obtain CPD credit in each of these three areas. Participation was low, however, and in 1984 the CPD program was dropped entirely (Batsche, 1990). While the NASP ethical standards recognize the obligation of school psychologists to participate in CPD, there is no minimum requirement for CPD activities in order to maintain association membership. APA established a continuing education program in 1975 (Hynd, Pielstick, & Schakel, 1981). The association focused its attention on establishing criteria and procedures for approving sponsors of more formal continuing education activities rather than specifying a minimum number of required hours of CPD, believing instead that state licensing boards should establish these criteria. APA continues to approve continuing education sponsors and has adopted a role as clearinghouse for CPD activities appropriate for psychologists.

At about the same time that the professional organizations were establishing continuing professional development programs, many states and regulatory boards began mandating CPD as a requirement for renewal of professional licensure (VandeCreek, Knapp, & Brace, 1990). The purpose of mandatory continuing professional development was to improve the quality of services provided to the public. Forty state boards of psychology required CPD by 1998, with several other states having plans to implement mandatory continuing professional development in the near future (American Psychological Association, 1998). The content of CPD is usually not mandated, although many states have specified that a certain number of hours must be earned in ethics. Increased accountability in public education has heightened the emphasis on continuing education for all public school personnel, including school psychologists, although state teacher credentialing systems have lagged in their requirement of CPD (Batsche, 1990).

While continuing education is most often discussed as a necessity to meet ethical, legal, and professional requirements, CPD also has personal, professional, and organizational benefits (Cervero, 1988; Houle, 1980; Hynd, Pielstick, & Schakel, 1981). Individuals can obtain enhanced personal satisfaction, improved skills, increased salary, job advancement, and increased adaptability to change. The profession gains enhanced public image, a mechanism for promoting professional competence and accountability, and increased adaptability to change. Organizations embracing continuing education may also have an enhanced public image and be viewed as a better place for employees, thereby promoting employee recruitment.

NASP establishes the ethical obligation of school psychologists to engage in continuing professional development. By virtue of membership in NASP each member agrees to comply with the Association's ethical standards. It is stated in the *Principles for Professional Ethics* (National Association of School Psychologists, 1997a) that

> School psychologists engage in continuing professional development. They remain current regarding developments in research, training and professional practices that benefit children, families and schools (p. 655).

Therefore, it is the ongoing obligation of the school psychologist to engage in continuing professional development as one facet of maintaining professional competency.

Similarly, APA's Ethical Principles of Psychologists and Code of Conduct (American Psychological Association, 1992) recognizes the need for ongoing education. It is stated in the ethical standards that:

> Psychologists who engage in assessment, therapy, teaching, research, organizational consulting, or other professional activities maintain a reasonable level of awareness of current scientific and professional information in their fields of activity, and undertake ongoing efforts to maintain competence in the skills they use (p. 1600).

That this is an ethical standard, which is an enforceable rule for professional conduct, attests to the importance placed by APA upon maintaining competence for the professional practice of psychology.

Continuing professional development is also a requirement for recertification and renewal of licensure. Most state boards of psychology require CPD for renewal of psychology licensure, and most state certification systems require documentation of continuing education for renewal of state certification. Nationally Certified School Psychologists (NCSP) must participate in CPD activities as a requirement for the renewal of the credential. Seventy-five hours of continuing professional development activities are required within a 3-year renewal cycle. A variety of activities are recognized, including formal workshops or courses, independent study, and research or professional service.

BASIC CONSIDERATIONS

Continuing professional development has been defined as:

> ...an ongoing process consisting of formal learning activities that (1) are relevant to psy-

chological practice, education and science, (2) enable psychologists to keep pace with emerging issues and technologies, and (3) allow psychologists to maintain, develop, and increase competencies in order to improve services to the public and enhance contributions to the profession (American Psychological Association, 2000).

To be most effective, CPD must be carried out in a planned and systematic fashion (Watts, Miller, Frederickson, Myers, & Hart, 1988). CPD must address the emerging issues and technologies that will affect the practice of the school psychologist in the present and the near future. Since school psychologists have varying degrees of competence in practice domains (Ysseldyke et al., 1997) a variety of levels and types of training must be made available.

School psychologists are ethically bound to engage in CPD activities and are responsible for their own continuing professional development. The most effective learning takes place when school psychologists are actively involved in planning their professional development (Fox, 1992). The construction of an individualized CPD plan is based on a four-step cyclical model that includes (a) setting the context and identifying needs, (b) prioritizing needs, (c) selecting and implementing developmental activities, and (4) evaluation and documenting activities (British Psychological Society Division of Educational and Child Psychology Standing Committee on Continuing Professional Development, 1992, cited in Presland, 1993).

Identifying CPD Needs

Self-assessment is the first step in creating an individualized CPD plan and assists the school psychologist in identifying his or her continuing professional development needs. The school psychologist must initially take into consideration several contexts in which they function. First, one should consider the current role and function, but then review what possible changes in role and function might occur in the future. Plans of the local school or school district for program change or expansion or pending legislative or policy changes that would affect the school psychologist's job duties must be considered. School psychologists should also take into account their overall career plans. They should consider what vision they have for future job changes or administrative advancement or for expanding into new practice areas. Individual reflection and talking with peers, supervisors, and administrators are all useful strategies in assessing the current and future context in which one will work. Consulting contemporary literature in the field will also assist the school psychologist in determining the emerging technologies and practice models that may shape school psychology practice in the future.

Once the context is set then the school psychologist can analyze the demands of the present position as compared to the current level of knowledge and skill. Identify the knowledge and skills needed to ensure effective practice in the changing role or function or to pursue career growth and development. Discrepancies between current knowledge and skills and those of the present position, predicted expansion in job role and function, and desired career development should form the basis of CPD needs.

Two structured methods might be of use to school psychologists in determining their learning needs. The critical incident analysis (Presland, 1993) has the school psychologist identify incidents in the recent past that created difficulties or could have been better handled. To do a critical incident analysis the psychologist writes a description of the incident, and then identifies the knowledge, skills, or attitudes that would be necessary to deal more effectively with the incident in the future. Checklists are another useful method of providing structure for the CPD needs assessment (Fowler & Harrison, 1994; Watts, Miller, Frederickson, Myers, & Hart, 1988). The Professional Development Needs Checklist in Table 1 is created to provide a starting point for identifying training needs. The checklist is based on the major practice domains identified as important for school psychologists (Ysseldike et al., 1997) and rating scales devised by Fowler and Harrison (1994) and Watts et al. (1988). The checklist is not exhaustive, and there is room for the school psychologist to expand on and supplement the items on the checklist to reflect his or her particular work context. To use the checklist, review each item in the practice domains and analyze their level of knowledge and proficiency in their current position and in anticipated or desired future roles.

While at first glance this seems a simple process, many often have difficulty assessing their knowledge

and skill deficiencies (Cochenour, 1992). Therefore, input from a variety of information sources can be beneficial. Having a supervisor provide a rating for items on the checklist and reviewing past performance appraisals needs can identify training. Input from peers, through informal feedback or completing the rating scale, can be useful. Consumer feedback and program evaluation surveys can also provide data for assessing training needs (Fowler & Harrison, 1994).

Prioritizing Needs

The CPD needs assessment process results in the identification of specific areas of knowledge and skills to be enhanced to improve current job performance, prepare for anticipated changes in role and function, and/or further the school psychologist's career development. The task now is to prioritize the identified needs. In determining priorities the following parameters should be considered:

1. Immediacy: Knowledge and skills necessary to more successfully execute one's current job are usually a higher priority. Needs that relate to anticipated changes in role or function or that further one's career development may have a lower priority. It is important for the school psychologist to have some CPD activities that are future oriented rather than focusing only on immediate training needs;

2. Frequency: CPD needs that have been identified by more than one source of information are likely to have a higher priority;

3. Impact: The training needs that are likely to have the greatest impact on consumers and/or the school organization may have higher priority than knowledge and skills that have a less dramatic impact.

4. Professional guidance: All school psychologists should have a high level of expertise in four practice domains: Data-based decision making and accountability; legal and ethical practices; interpersonal communication, collaboration, and consultation; and student diversity in development and learning (Ysseldike et al., 1997). Deficiencies in these areas should receive priority for CPD. Needs in other practice domains will vary in priority based on the school psychologist's current and future job and career situation.

5. Personal interest: Other things being equal, training needs reflecting greater professional interest to the school psychologist are more likely to be actively pursued.

The end result is a list of training needs in priority order. The next task is to identify and implement activities that would meet the identified learning needs.

Selecting and Implementing Developmental Activities

A variety of learning activities are available to meet CPD needs (Fowler, 1996), many of which are regularly listed in the NASP *Communiqué* and APA *Monitor on Psychology*. Formal courses seminars and conferences are the traditional types of CPD activity. They are appealing in that they are organized, time-limited, and are especially useful when the practitioner needs to develop basic knowledge and skills. There is the risk of taking these activities for granted, however, in that one can fail to utilize the material covered when returning to the work environment. Informal and self-directed learning activities include individually planned study of books, journal articles, or other audio-visual materials. A number of semi-structured topical self-study programs have been developed by NASP and APA and are also available through a variety of private vendors. To gain maximum benefit from informal and self-directed learning activities the resources must be high quality and up-to-date, and the learning objectives of the activity must be congruent with the needs identified in the CPD plan.

A variety of other professional activities that extend beyond the demands of the school psychologist's primary employment may also make a valuable contribution to a CPD program. Peer support groups can be organized to foster learning and problem solving (Zins, Maher, Murphy, & Wess, 1988). Developing and presenting training programs, teaching college/university courses, and conducting research and then publishing can benefit both the school psychologist and the profession. Supervision of interns and professional organization leadership can enhance professional knowledge and skills. School psychologists may have the opportunity to participate in post-graduate supervision as a part of their employment or outside of their primary job setting. Each of these activities must occur in a planned fashion, be congruent with the individual's training needs, and focus on the professional growth of the individual school psychologist.

Distance education provides new options for CPD. Distance education involves learning activities in which the learner is separated from the instructor or educational institution (Miller, Smith, & Tilstone, 1998). This can include formal activities such as an organized course or structured self-study program, or informal activities, such as an on-line forum or professional discussion group. Distance learning activities have been well received because of their convenience for persons who may live some distance from a training site. On-line forums have been found to provide flexibility in time constraints, time for reflection, and opportunities to do further research on topics discussed in the forums (Anderson, 1996).

Once potential CPD activities are identified, it is the responsibility of the school psychologist to determine whether the activity will be appropriate for the training need. A useful method of evaluating the appropriateness of a potential CPD activity is adapted from a series of questions provided by the NASP Continuing Professional Development Program (National Association of School Psychologists, 1996):

1. Will the CPD activity enhance or upgrade professional skills or knowledge base?

2. Will the activity be relevant to the professional practice of school psychology?

3. Will the activity fit into the priorities of my personal plan for CPD?

4. Will the activity extend beyond the ordinary aspects of my current job duties?

5. Will the activity involve active learning strategies such as problem-solving, discussion, case studies, simulations, role playing, and reflection on practice?

6. In the case of formal activities, does the developer of the activity have a reputation for high-quality training activities? Do other school psychologists who have participated in the activity provide positive recommendations?

Affirmative answers for each of these questions for an activity under consideration will increase the likelihood that an identified CPD activity will make a positive contribution to the CPD plan.

Evaluation and Documentation

Evaluation of CPD activities should be an on-going activity. The real impact of continuing professional development is not completing an activity or meeting an external requirement for CPD hours, but whether the activity improves professional competence and furthers career development (Fowler, 1996). By evaluating the effects of participation in CPD activities the school psychologist can increase the likelihood of incorporating new learning into everyday practice. Evaluation also establishes progress toward meeting professional development goals, and information from the evaluation is then another source of data to use in planning future CPD activities. Systematically developed training needs and goals form the basis for effective evaluation activities. Two broad categories of evaluation should be addressed: implementation issues and outcome issues (Cervero, 1988).

Implementation questions assess the process of learning and participation during the activity. Active participation in learning and reflecting on practice are important to effective professional development. Activities that have clear objectives and learning activities consistent with the objectives will be most useful. Active involvement in learning and completing the learning activities as designed will result in maximum benefit from the activity. Most CPD activities have stated objectives. You should ascertain if the objectives of the activity are clear. The components of the program should be consistent with the objectives. You should complete the activities and requirements as outlined by the program. You should be an active participant in the activity.

Outcome questions address changes that result from the CPD activity. Continuing professional development activities that result in changes in knowledge, skills, and attitudes that enhance professional practice and services to consumers are the most beneficial activities. You should assess what was learned and what changes in knowledge, skills, and attitudes have occurred. Assess how you can apply these changes to your practice and what the impact is of any changes in practice. Ensure that what you learned in this activity enhances your career development. Verify that these changes are consistent with your CPD goals and career development plan. While many outcome questions can be answered by personal reflection and analysis, supervisory feedback, peer and consumer evaluation, and review of services documentation may all be useful in evaluating the impact of new learning on practice.

The results of a systematic evaluation will enable school psychologists to effectively manage their continuing professional development. Evaluation becomes a meaningful part of the CPD cycle when evaluation results are used as data in determining learning needs and goals. A CPD activity that does not effectively meet the identified learning goals can be discontinued, and a more effective activity can be substituted. The process of evaluating learning can foster greater involvement in professional development. Evaluating continuing professional development may also have a positive effect on an employee evaluation, as one's supervisor or employer may view this as an indication of the school psychologist's commitment to provide high-quality services.

Professional accountability requires that CPD activities be documented. A record should be kept of all CPD activities including workshops, conferences, and self-study activities. Letters of verification, certificates of completion, and documentation of continuing education credits serve to verify completion of formal activities. A detailed record of learning objectives, activities completed dates and hours of participation, and method of evaluation should be kept for self-directed or informal learning activities. Where CPD activities are required for renewal of licensure or certification, the school psychologist should be familiar with the requirements and the particular method of documenting and reporting compliance required. NASP offers an automated CPD system that allows CPD activities to be tracked as they are completed and submitted. Each year a transcript that provides a summary of CPD activities is sent to participating members.

Staff Development

The NASP *Standards for the Provision of School Psychological Services* (1997b) establishes the obligation of employing agencies to encourage and support CPD for school psychologists. The focus of continuing professional development from the organizational perspective is to build the capacity of individual practitioners to meet the specific needs of the organization (Trotta, 1995) and develop the capacity of the organization as a whole (Ferguson, 1999). Staff development activities can make a valuable contribution to changes in employee behavior and service provision, but are not a substitute for effective leadership, adequate organizational resources, or supervision (Todd, 1987).

Staff development activities often take on a supermarket model where individual school psychologists apply for staff development funds, attend courses on a first-come, first-served basis with little coordination among psychological services team members (Miller, Watts, & Frederickson, 1988). Fox (1992) recommends that staff development begin with an evaluation of individuals' training needs and then take into account the goals and needs of the organization. Planned Professional Development (PPD) (Miller, Watts, & Frederickson, 1988) is one example of combining individualized CPD with organizational needs to develop a more efficient use of staff development resources.

PPD begins with each school psychologist completing an assessment of his or her individual CPD needs by using a checklist such as the one in Table 1. At the same time management staff completes a list of development needs for the school psychological service taking into account external needs and demands on the service. In the case where school psychologists work in teams, each team meets to identify team development needs. The identified needs are then collated on a tally sheet and compared to the priorities and mission of the school psychological services group. From this list staff development priorities are developed through group discussion and negotiation. Priorities are assigned by giving the highest priority to those needs that are common to many school psychologists and have the most congruence with service needs. While there is typically a significant overlap between the CPD needs identified by individual school psychologists and the service needs identified by the school psychology supervisor, it is important to make sure that neither individual nor organizational needs be given exclusive priority. Once priorities are established, each school psychologist then completes an individual CPD plan and the school psychology supervisor develops a service development plan. The plans are implemented and evaluated for effectiveness in meeting the identified training needs.

Professional development can be an important part of planning for organizational or services changes. Organizational change accompanied by effective CPD is more likely to be effective because practitioners then have the requisite knowledge and skills to support changes in organizational structure and services (Frederickson, Miller, & Watts, 1990). Presland (1993) provides a description of a CPD day process (actually occurring over several days) whereby the school district's psychological services unit systematically considers the likely scenarios for the future and how the service might respond to the anticipated changes and demands. School psychologists meet to identify and review the national and state trends and local priorities for the future. They create a series of possible future scenarios and brainstorm a list of individual services that might be offered to clients in the future scenarios. School psychologists as a group then consider the service priorities. Each psychologist identifies his or her individual CPD needs by using a critical incident analysis and CPD checklist, and school psychologists who work in teams develop an intermediate plan describing the prioritized needs of the team. Then a staff development plan is developed for the entire school psychological service, providing relevant choices of CPD activities for individual psychologists.

These are but two examples of how individual CPD plans can be coordinated with the needs of the entire school psychological services group. They offer the benefits of widespread participation, promotion of CPD, and stimulating future thinking. More efficient use can also be made of the limited time and resources available for staff development and CPD.

BEST PRACTICES

1. School psychologists must make a commitment to be lifelong learners, recognizing that CPD is a professional obligation to oneself, the profession, and consumers.

2. Each school psychologist should have an individualized CPD plan.

3. School psychologists should engage in a regular evaluation of their training and continuing professional development needs, taking into account the demands of their current position, anticipated changes in the workplace, and their career development plans. The needs assessment should be on

going and involve supervisors, peers, and/or consumers.

4. Continuing professional development activities should be selected to be consistent with the learning needs and goals that were identified in the needs assessment.

5. A variety of CPD learning activities should be considered. Each activity should be evaluated as to its quality, appropriateness, and potential impact on learning.

6. School psychologists should strive to be active learners. CPD activities that foster involvement in problem-solving, discussion, case studies, and skills practice will be the most effective learning tools.

7. School psychologists must evaluate the implementation and outcomes of CPD activities. Determine if the activity was completed as proposed, whether the learner was actively involved in the learning process, and if the activity met the stated objectives. Identify what was learned and what impact the learning had on practice or career development.

8. Administrators and supervisors of school psychological services should acknowledge the importance of continuing professional development for their staff and provide resources, support, and recognition for participation in effective CPD activities.

9. Administrators and supervisors of school psychological services should involve school psychologists in assessing the training needs of the school psychological services unit and generate staff development activities to enhance the capacity of the entire services unit.

10. School psychologists and administrators must recognize that organizational change and continuing professional development go hand-in-hand. Changes in practice are only possible when professionals have the training necessary to carry out new roles. Continuing professional development activities should be a part of planning for organizational or practice changes.

SUMMARY

Pre-service training in school psychology provides practitioners with an initial base of knowledge and skills for professional practice. Psychology and education continue to rapidly evolve, incorporating innovative technologies, changing expectations, and new information. School psychologists have an ethical obligation to maintain professional competence, and CPD activities are generally required to renew professional licensure or certification. Continuing professional development activities allow the school psychologist to maintain effective practice, respond to changes in the workplace, and prepare for career advancement.

Effective continuing professional development is a continuing activity that involves a four-step process: (a) setting the context and identifying needs, (b) prioritizing needs, (c) selecting and implementing developmental activities, and (d) evaluation and documenting activities. A variety of formal and informal CPD activities are available, and professionals should select those activities that offer active learning strategies such as reflection, discussion, case studies, and skills practice. Evaluating the impact of CPD on knowledge, skills, attitudes, and impact on practice is important. Information from evaluations can be used to update the CPD plan.

Administrators and supervisors of school psychological services have the obligation to encourage and support CPD activities. While the traditional focus of continuing professional development has been on building capacity within individuals, CPD can play an important role in developing the capacity of the entire service unit. Changes in role and function or expansion of services typically require that professionals acquire new knowledge, skills, and/or attitudes. Consequently, professional development activities should be included when planning organizational change or services expansion.

A two-part series that provides materials and a process for identifying the continuing professional development needs of school psychologists and school psychology services units. The approach is novel and useful for both individual and organizational planning.

14 Best Practices in Technology

William Pfohl and Virginia A. Pfohl
Western Kentucky University

OVERVIEW

A remarkable progression of technological advances has occurred since 1975. From the development of the computer chip to the rapid expansion of the Internet, computer technology has significantly affected everyday life. Homes now feature high tech capabilities in everything from appliances to cable television. Computer networks, distance learning, and word processing have altered professional lives, as have the educational mandates for assistive technology in Individuals with Disabilities Act.

Education has started to embrace technology as a way to facilitate learning and connect students to the larger world. Therefore, it is critical that school psychologists not only acknowledge technology's advantages but master its nuances.

This chapter will review basics of current technology (as of 2001); that is, how to select it, how to maximize its use, and how to maintain professional ethics while doing so (see Table 1).

Currently, school psychologists deal with technology on three fronts: personally, professionally, and educationally.

Professionally and educationally, new opportunities for school psychologists have evolved with access to distance learning courses over the Internet, web-based university course work, or peer-to-peer consultation opportunities (such as those provided by Global School Psychology Network), and psychologists can interact or receive supervision or consultation from others in different states or even countries. Many school psychologists regularly use computers for scoring programs, word processing, and record management. Many of the new test instruments now come with scoring software. In the classroom, students and teachers have begun taking full advantage of the Internet and its capabilities. Handicapped and

Table 1. Guidelines for school psychologists using technology

- Select hardware and software wisely
- Make a commitment to become more computer and technology literate
- Use technology for personal and professional growth
- Keep abreast of new issues regarding legal and ethical use of technology
- Be aware of uses of technology to help students and teachers learn more efficiently
- Review or conduct research on the effectiveness of technology in education
- Provide guidelines to educators and parents on uses and dangers of technology
- Protect and use data responsibly and ethically
- Make sure information gleaned from Internet sources is factual and from a known authoritative source.

disabled students also benefit from touch pads, voice-activated devices, electronic artificial limbs and devices, and electronic voice synthesizers. All students can now use technology for electronic portfolios, testing, data storage, and classroom projects. Teachers now routinely require computer-based assignments, Internet exploration, and software knowledge from their students.

School districts have also gained from Internet access. Students in poorer schools have benefited from state and federal funding and from P. L. 101-407, which was signed in 1988 (Technology Related Assistance Act). E-cost accounts in school districts now provide low-cost Internet access to many districts. Research needs to be done to evaluate the best way to use this new technology to help students learn.

On the down side, with all the rapid advances in technology, computers and software quickly become outdated, leaving the educational community continually playing catch up. Sometimes, few trained personnel are available to help educators and school psychologists understand the complexity of technology and how to use it most effectively. Schools and educators need help with setting up networks of computers, and many teachers do not understand or receive training in technology and its uses in facilitating student learning. All of these innovations potentially place school psychologists at a disadvantage if they do not keep pace with these technological changes and make a commitment to utilize technology in their personal and professional lives.

The U.S. Department of Education in 1996 outlined four technology principles for schools: (a) all teachers will have the training and support they need to help students learn to use new technology, (b) all teachers and students will have modern multimedia computers in the classroom, (c) every classroom will be connected to the Internet, and (d) effective software and on-line–learning resources will be an integral part of every school curriculum. The U.S. Department of Education is currently revising those goals to reflect the need for research on the best ways to use technology in schools and to help prepare children for the intellectual and moral demands of technology (Trotter, 2000). Those goals, or "pillars," will have a large impact on education and indirectly on school psychologists.

Despite the wider availability of and enthusiasm for technological advances, technology has not yet benefited everyone. It was stated in *Education Week* (2001) that "...surveys identify the kinds of students who appear to be losing out when it comes to technology. For a variety of reasons, those students include poor children, minority students, girls, low achievers, students learning to speak English, children with disabilities, and youngsters who live in rural areas" (p.11). All these students are typical of those served by school psychologists. Getting technology's advancements into schools and to all students has proved challenging. (Yearly, *Education Week* publishes a "Technology Counts" review and status for each state, indicating its progress toward providing technological advances to the state's districts.)

WHY TECHNOLOGY?

As our society moves from an industrial/manufacturing focus to a knowledge-based one, it is imperative that people become comfortable with technology for knowledge acquisition, data storage, and connectedness. Education reform movements, a global emphasis on learning, and an international economy have dictated the use of technology for learning, communication, and e-commerce. Technological advances have enhanced time management and business productivity. Hand-held computers or Personal Digital Assistants (PDA) have sold more than 2.5 million units in 3 years (1999–2001). The World Wide Web (abbreviated as WWW in a website domain name) has provided ready access to information that previously was available only at large universities, libraries, and medical centers. Parents and students now have access to much of the same information as school psychologists on various disorders, learning issues, etc. In addition, the capacity to do research and statistical analysis is now available on computers in the school district.

The remainder of the chapter covers these main ideas: selecting hardware and software, assistive technology, the Internet, ethics and technology, and the future of technology and school psychologists.

SELECTING HARDWARE AND SOFTWARE

Unfortunately, or fortunately, technology advances too quickly to adequately illustrate the usefulness of certain products. What is selling today probably will not be selling in two years, and the technology described today probably will radically change in a manner of months. With that in mind, this section will attempt to give an overview of what basic hardware and software are available (as of 2001) and how to choose the appropriate hardware and software for your needs. Of course, many will know all this material, because they are familiar with computers and the Internet and with technology already. However, there are still many who are not yet comfortable with computers and are stymied or are overwhelmed by what these technological words mean and the myriad choices of what to buy.

Hardware

Computer technology will continue to improve rapidly, but some main principles still guide its selection. First you have to define your needs. What do you want the computer for? Do you want it for researching on the Internet? Do you need it to help you score tests? Do you need it for word processing? Then you have to ask yourself how much you are willing to spend. Almost any priced computer will provide adequate word processing for reports or scoring of test protocols. For more advanced capability, such as PowerPoint® presentations, multimedia learning, accessing electronic books, or digitized video or training programs, a more powerful computer will be required.

DESKTOPS, LAPTOPS, AND PDAS

As of 2001, three computer types exist: desktops, laptops, and hand-held computers (PDAs). Intended use, of course, will dictate choice. Presently, desktops and laptops are available in two configurations, IBM-PC and Macintosh (Mac). Microsoft uses IBM-PC. Apple uses Mac. However, as the Internet grows, more and more software will be on the Internet, and more computers will be run from the Internet.

Some basic principles apply in looking for either a desktop or laptop computer. The budget-priced computer, usually purchased for the home for word processing, e-mail, and Internet access, typically offers basic operating software and limited expandability. These computers are optimized for the Internet, and capable of word processing and protocol scoring. A little careful planning and consideration will prevent disappointment and unnecessary spending later on. These low-cost machines are usually best suited for the young school student or for home use. However, as technology advances, so do the capabilities of these machines, and what was state-of-the-art a year ago is now an entry-level machine today.

For a few hundred dollars more you can buy a more technologically advanced desktop that will offer an increased ability to expand or to modify the configuration. However, as has been proven in the marketplace, many consumers prefer to buy a new computer rather than upgrade their existing computer. This is because of compatibility problems with OEM manufacturers and the chips or cards you can buy at a retailer and the cost and complexity of upgrading. Again, the planned use of the computer will determine what capabilities and add-ons are needed. Playing advanced multimedia games, using digital cameras or scanners, all require high capabilities. In this case, the best guideline is to buy the best computer you can afford that has all the capability currently available on the market at the time of purchase. This allows for the most compatibility between the various computer components and will be cheaper in the long run. A larger monitor or LCD screen, more RAM (random-access memory), and larger hard drive are worth serious consideration at the time of purchase.

The vast majority of users use IBM-compatible computers and software. However, because Apple made a marketing choice years ago to virtually give their machines away to schools, many in the education field still use them. Mac is easy to learn, easy to use, and is still the PC of choice for designers and artists. However, for school psychologists, psychologically oriented software for the Mac is still limited, particularly for protocol scoring. If your district uses the Mac platform, then Macs may be a wise choice for ease of use and data and software compatibility, but scoring software issues may still remain.

Laptops are more expensive than desktops but more efficient for school psychologists because we are typically on the move. Weight and durability will be important features. Laptops, depending on features, can be bought in a variety of configurations from the most basic to extremely powerful, equivalent to a desktop. Hardware features, such as CD-ROM or an extra battery, can add significantly to both weight and cost. The laptop needs to be purchased together with a network card that is compatible with the school district.

Major disadvantages to a laptop are short battery life and having to swap various components (floppy disks/CD-ROM, batteries). If this laptop computer is to be used for multimedia presentations, such as PowerPoint®, then more powerful components (e.g., more RAM and larger LCD screen) will be needed. Batteries tend to be a problem, so purchase the best technologically advanced battery available. Laptop companies are working on battery technology constantly. In addition, theft and the risk of dropping the machines are the biggest drawbacks to any laptop. Because they are portable, laptops are stolen at the rate of more than 500,000 per year (2001 data). Leaving a laptop in a car, in an office, or other location can result in losing not only the laptop but also its confidential data. Dropping a laptop can also destroy data by affecting the hard drive access. Regular data backups are essential so that data are not lost. Backup data regularly to a disk or other media device. Make sure that any psychological files on the school's network are also backed up regularly and kept confidential.

The PDA (hand-held computer), as of now, is limited in what it can do. School psychologists may find that a PDA offers a portable, technologically advanced alternative to carrying a large appointment book. Simple word-processing can be done on the PDA, but it is tedious. PDAs are good for notes, memos, and keeping track of expenses and appointments and maybe IEPs or ITPs. There are also add-ons available, such as satellite e-mail. Software programs are currently available for download from the Internet, such as word processing, databases, spreadsheets, and scoring software. This technology will expand and become more reasonable in cost. The PDA technology allows data to be regularly backed up in just a few seconds onto the desktop or laptop computer before the PDA is lost, stolen, or broken.

A surge protector with telephone modem jack protection for both laptops and desktops is essential. The surge protector should include a warranty for full replacement coverage for the computer. Look for a surge protector that will adequately protect your machine. Here, cost is a factor. The better surge protectors cost more and will do a better job. Better yet, there are battery back ups, by APS and others, that do a great job in case of a blackout or a surge. Remember, more expensive is usually better. An ordinary power strip or an inexpensive surge protector, one that costs less than $20, is not adequate.

MODEMS

Modems are devices for connecting either telephone lines or cable to the computer and are available in a wide range of prices and features. Most computers come with a telephone (dial-up) modem and/or a network card combination. Typically telephone modems transmit at a speed compatible with typical copper phone lines. As more fiber optic lines become available, this speed will increase. Cable modems from cable companies are faster than telephone modems as are Digital Subscriber Line (DSL) connections. DSL is available through phone companies and through third-party bundlers. Satellite or wireless Internet access connections will be widely available in the next few years. They are now available for PDAs for a monthly fee. Most technology authorities feel that wireless will become the standard.

PRINTERS, SCANNERS, AND USB PORTS

A wide variety of printer choices are available. Therefore it is important to determine how the printer will be used. There are two kinds of printers: ink jet and laser. Ink jet printers are less expensive initially but are more expensive to run because of the expense of the ink jet cartridges. Ink jets print in color, and the printing is near the laser in quality. Lasers are more expensive initially, especially the color-printing ones, but the laser toners last longer than do ink jet cartridges. Many choose black-and-white lasers because of the expense of the color ones. However, the quality of the printing for lasers is excellent. Laser printers are generally used in offices and in art shops and are best for network sharing or larger volume printing because they are faster and because of the printing quality.

Portable printers, typically ink jets, are adequate for text printing but are expensive per page. They are available for computer formats. Connecting to the district's computer network will provide printer access, minimizing or eliminating altogether the need to buy a stand-alone printer. A scanner is used to copy other documents and then store that document on the computer. Pictures and graphics do require large data storage capacity.

A USB (universal serial bus) hub, attached to the computer, will allow all these hardware options to be connected to the same computer without extra connector ports.

PURCHASING

Hardware can be purchased locally or on the Internet from retailers (IBM, Compaq, etc.) or on the Internet or by phone from the manufacturer (Dell, Gateway, etc.). Although computers bought directly from the manufacturer can be customized for your needs, it may be best to buy from a local brick-and-mortar retailer if you are buying for the first time. But remember that retail personnel may know not much more than you do and may try to push a machine that they have been told to push. (Manufacturer personnel (Dell, Gateway, etc.) over the phone, from experience, are extremely informative and knowledgeable, but only about the brand they sell.) It may be best to take along someone who has knowledge of computers. You should buy a name-brand computer rather than a no-name or store-brand computer.

Buying a computer is not a difficult decision. Most name-brand computers are similar in what they offer and in their warranty. Some computer brands are more reliable than others. *Consumer Reports* and PC magazines reviews are good guides to use.

In summary, here are a few basic guidelines when purchasing your first computer:

1. Decide your use.
2. Decide your price point.
3. Decide which operating system to use (IBM-PC (Microsoft) or Mac (Apple)).
4. Decide what kind of machine you want to buy: desktop or laptop.
5. Decide where you want to buy it: directly from the manufacturer or from a retailer.
6. Understand the company's return policy.

Software

Most software is bundled and is sold with the computer. Most manufacturers use Microsoft software. This makes it very easy to share information with colleagues. Software comes in packages, called suites, or as stand-alone pieces. Suites typically contain a word processor, presentation application, spreadsheet, and database. Some suites offer more advanced features for an additional cost. There are three suites currently available: Microsoft's Office®, Corel's WordPerfect Office®, and IBM's Lotus Suite®. All work well and will handle a school psychologist's needs for writing and storing information.

Scoring software, which makes the school psychologist's life much easier, is widely available for the IBM-PC format. It is less so for Mac.. Site licenses are important if the software is to be used by more than one individual or on more than one computer. Please inquire about this within the school district. A wide variety of school psychology–focused software is available including protocol scoring, test administration, report writers from book and test publishers and from outside vendors. This software needs to be evaluated very carefully, similar to inspecting a new technical manual from a test kit. Ethics require that the psychologist be aware of the strengths, weaknesses, and accuracy of these scoring and/or report writing products. These will be discussed in greater depth in the ethics section.

Powerful statistical packages, such as Statistical Program for the Social Sciences (SPSS), now are user friendly and are available to run on desktop and most laptop computers. This software would handle any research and statistical analyses needs.

Another important software purchase is a utility program suite, usually including anti-virus software, computer diagnostic utility, maintenance, and security utilities. These programs provide the ability to protect, maintain, and service various problems with the computer. Virus detection software is essential for anyone using the Internet or e-mail, and it is *critically* important to keep this software up-to-date (monthly). Some utilities come with computer maintenance software to help the computer run more effectively and efficiently. Windows has some built-in features (Diskscan and Defragmentation), but they are not the most current or sophisticated versions available. Access to the Internet through a DSL or cable modem ("always on" mode) requires an Internet security software program ("firewall") to keep others from accessing the computer and causing damage or stealing private or personal information.

Netscape and Internet Explorer are popular web browsers (explained in detail later) and provide access to the web and are often installed already when you buy your computer. Besides a web browser, other software packages are helpful when using the Internet. For instance, Adobe's Acrobat Reader, free from their website, translates files that are written in PDF (portable document file) format. (Much of NASP's webpage has PDF type files.) The advantage of PDF format is that it cannot be modified except by the author and when printed out it looks exactly like the printed page from which it was taken.

Shareware and freeware are other software that is available to the school psychologist. It is found on the Internet. It is often of excellent quality but is at a lower cost or may be free.

Many commercial software programs in a package are available to faculty/staff/students at the local university bookstore at a substantial savings, typically 25–50% off retail. These are specially priced, complete software packages (not upgrades) direct from the company. Other sources of software are through the Internet (shareware, freeware, and e-commercial software stores), on-line services (such as America Online), retail stores, and local public libraries. Software and hardware purchases take time and knowledge. Find somebody knowledgeable to help if necessary, shop for features, and buy all the hardware together to help ensure compatibility. The key element to obtaining software is *compatibility* with the computer hardware and other software.

ASSISTIVE TECHNOLOGY

Assistive technology is an area of considerable importance to all school psychologists. Under the Individuals with Disabilities Act (IDEA 97), technology is mandated to help enhance learning opportunities for handicapped students. Two elements are defined in IDEA 97 for assistive technology, devices, and services. Devices are equipment related, while services, for example, indicate any modification of environments, adapting assessment procedures, or training others to work with the handicapped child. Pfohl and Craycroft (1999) outline the various principles for using assistive technology with handicapped students. The guidelines state that a child first needs to start with a low-tech modification and then move onto a more high-tech method as individual cases dictate. Modification of a pencil or writing instrument would take precedence over buying a computer; that is, if the child's educational goals can be met by the former.

Using computers or adapting the environment are both forms of assistive technology. Sometimes it is necessary to combine these and modify the device. A simple modification of the computer screen can be done by using Windows' Accessibility Option within the Control Panel. There are many features any child may benefit from in particular. These functions may help a visually impaired, motor impaired, or hearing-impaired child, or a child who has to have the keyboard responsiveness modified owing to motor control problems.

Assistive technology, either devices and/or services, must be outlined in the student's Individualized Education Plan (IEP) (Cunningham & Kelly, 1998). The amount of time, length of services, and specific device to be modified or used need to be indicated. A computer can also be used to collect the evaluation data for IEP goal(s) attainment.

USING THE INTERNET

To use the Internet, it is first necessary to get on-line. This is done through an Internet Service Provider (ISP) by using a computer modem on a telephone connection, a cable, or a DSL line. The modem connects the computer to a server at the ISP computer, which then links to the global network of computers called the Internet. A stand-alone ISP provides basic dial-in service and is different than an online service, which provides many additional features, such as news, shopping, weather, and sports. America Online (AOL) and Microsoft Network are two of the many on-line services. (It may be easier to think of AOL, for instance, as a large magazine with various articles, a *TV Guide* of the Internet. *TV Guide* tells you what's on, gives you opinions and ratings, and what channel the program is on. That's what AOL does. A stand-alone ISP merely gives you, to use the same analogy, a television and a remote. You decide what you want to watch, and then you find the channel the program is on.)

E-mail

A popular on-line activity is sending and receiving e-mail. Mail, even with attached files and photos, can be sent around the world instantly to another person's e-mail address (typically username@the ISP.com). It is fast, cheap, and has changed how people communicate. An entire culture of e-mail "netiquette" and humor has emerged. A single message can be sent to many addresses simultaneously: groups of friends, colleagues, employees, family members.

E-mail has made personal and professional communications easier, yet has its disadvantages also. Users complain of being overwhelmed by the number of e-mail received and the amount of time needed to read and process them. In addition, e-mail is used by commercial companies as an inexpensive method of sending huge quantities of electronic junk mail (or spam). E-mail also has potential ethical consideration, discussed later. Some ISPs allow you to block unwanted e-mail.

Accessing the Internet

Another reason to go on-line is to access the Internet. The Internet is composed of six components. Most people are only familiar with the web. The other five are Gopher, WAIS, ARCHIE, FTP(file transfer protocol), and newsgroups/FAQ (frequently asked questions).

The Internet is actually a collection of computers across the world, mostly government or university based, which store information or data on a vast array of topics. The Internet was primarily developed in the 1950s to facilitate military and university research and communication in case there was a war-related disruption of the normal methods of communication. Since the Internet consists of multiple accesses and computer networks, it is impossible to monitor or control all the facets of the Internet.

A web browser software package is necessary to use the Internet. Microsoft packages their browser, Internet Explorer (IE), with their Windows OS. PC computers with Windows will come with this installed. Netscape and Oasis are two good browser alternatives. Some websites are "tuned" for a particular browser, so that all the site features may not be available for other browsers. The Oasis browser is capable of working on older computers and takes little hard disk space. Netscape is free, and Oasis charges a small fee when it is downloaded.

All sites are given a *code* that identifies them. On the web, this code—known as a Uniform Resource Locator (URL) or address—is entered into the browser to find the desired site. The URLs for the web include the prefix (http://), which tells a host computer to look for a specific web page. If not certain of the specific address (*it must be exact*) then use a search engine to help locate the desired or similar sites. Search engines can use words, phrases, or sentences to find the desired information (e.g., ADHD, stimulant medications). Since each site performs searches differently, read their instructions for searching at that particular site.

With the increase in the commercial trade on the Internet, many sites trying to sell a product use search word descriptors that will cause a search engine to list their site even though it may be totally unrelated to the desired search.

SURFING THE WEB AND THE SCHOOL PSYCHOLOGIST

One popular characteristic of the web results from "hyperlinking" (typically words or URLs highlighted in a different color and underlined), which can send the user to another place on that site, provide additional text, transfer a user to a different or related site, or offer related information without having to know the specific URL (this process is called "surfing"). Saving "bookmarks" within the browser software helps the user return to sites that are most useful and frequently visited.

A downside of surfing the Internet is the possibility of addiction. Many adults, teens, and some children have become addicted to the Internet, spending excessive amounts of time surfing the web. This problem needs to be explored with those who cannot control themselves. The school psychologist must be aware of this new addiction, in addition to alcohol and substance abuse. Mental health treatment may be necessary.

Parents now use the Internet to gather information on various medical, developmental, and mental health conditions, and often bring printouts to the school psychologist's office or teacher's classroom. Unfortunately, information on the web has no quality control: anyone can post information, whether accurate or not. All printouts have the URL on it, so go to the site to verify the information. Check to ensure that the information is current, accurate, and from a reliable source; that it has a knowledgeable author; and that it is statistically valid. Unfortunately, many often believe that since they found it on the web, it must be accurate and authoritative. Never accept the information at face value. However, there are many excellent sites with accurate information that provide a wonderful resource for parents and professionals alike. (See www.nasponline.org for verified links.)

Creating Websites

Most school districts have a website. In addition, some districts' school psychological services (e.g., in Syracuse, N.Y., and in New York City) have built their own websites. A website may provide teachers, parents, or other community members with important information about children's learning and mental health issues. Building a website requires an ISP or school network to access the Internet and also web-development software that will translate information into HTML (hypertext mark-up language) format for posting on the website. The word processing software in the office suites by Microsoft, Corel, and Lotus, mentioned above, can be used for this purpose, but will create only a basic web page. All ISPs offer web page–building capabilities. ISP sites host the website and may offer additional software to make your website a bit more sophisticated. Web page making software within Windows or other software is getting easier to use.

Internet Privacy

Protecting privacy and identity on the Internet has become a significant issue. Identity theft and access of personal/professional information stored on computers is a growing criminal problem. The increasing value of e-commerce makes companies want to identify potential customers and gather personal information on them. Every time a computer connects to a website it sends out an identifying code This information includes the specific user's "user name" and personal ISP address. This information is "harvested" in a variety of ways.

Some websites send *cookies* back, which are short files that identify the user's computer to the selected website. Cookies are often needed to purchase items on the web, so that verification of the customer can be made. These can be deleted after the transaction or they stay on the hard disk until they expire. Cookies may hold a customer's password and username, remember a previous purchase, and even what other sites that computer has visited. On some web pages, there may be more than one company simultaneously using a banner ad or click-on box, or selling various related products, which all use cookies for their files. Cookie management can thus become a problem. Most browsers allow the ability to control cookies by adjusting the software to select from options that range from completely blocking cookies to accepting all of them.

Most individuals want to protect their privacy, but using the Internet can compromise that. There are complicated ways to hide your identity, but otherwise your footprint is left where you go on the Internet. A look at the end of an e-mail message will tell where it came from and how it got there, all of which is public information. Any time software is registered using the Internet, the host site keeps a record of the identifying information. Microsoft has been particularly inefficient with its software security. A "cyber hole" has existed for a long time in their website, and this can allow for registration information to be harvested by outsiders. Be sure to read all privacy policies carefully upon entering any site. Privacy is a significant issue for Internet users. Protecting personal and business information is worth careful consideration.

Shopping on the Internet can cause privacy problems if the shopping site is not secure. When connected to a secure site, a "lock" icon should be visible in the locked position. Credit card information can safely be transmitted. If there is not a lock, then the connection is not secure, and then make a phone call to the person or company you want to do business with.

Computer users who have either a network or cable/DSL always-on connection should install a firewall. This prevents hackers from breaking into the computer and accessing data on the hard drive. Software, commercial or free, is available to set up a protective firewall.

Viruses

One critical issue is viruses. So far Microsoft's software (Word®, Outlook®, and Outlook Express®) is most vulnerable to privacy and virus problems (because of their wide usage) but there have been PDA viruses too. Microsoft Word documents and Outlook sent as e-mail attachments appear to be vulnerable to transporting viruses. Good virus protection software is essential for safe downloading from the Internet or getting e-mail attachments from friends and colleagues.

Web Databases

The Internet contains various databases that store information useful to school psychologists. The newest innovation is the *virtual library*, where full text articles can be found. Universities have established virtual libraries to offer complete books, journal articles, and other archival information on the Internet.

ERIC is the largest educational resource database. AskERIC (www.Askeric.org), will answer most educationally related questions. The 17 ERIC Clearinghouses have their own resources, listed at www.accesseric.org., and ERIC/CASS (Counseling and Student Services Clearinghouse) at www.ericcass.uncg.edu has a site with 12 different topics. ERIC also has a large virtual library website at www.askeric.org/virtual.

Other databases are at various federal government sites (indicated by a .gov ending). The primary master website for all the U.S. Government's websites is www.firstgov.gov. The U.S. Department of Education site, www.ed.gov, is a very inclusive site and is perfect for the general public and educators on child learning–related issues. The National Center for Educational Statistics, www.nces.ed.gov, has every educationally related statistic collected by the government. Mental heath information can be found at www.mentalhealth.org. The National Parent Information Network, http://npin.org, is a full database on issues related to child rearing and child development from birth to teens. Center for Disease Control, www.cdc.gov, has much information on health care and health education particularly mental health, and so does the National Institute of Health, www.nih.gov, and National Institute of Mental Health, www.nimh.nih.gov. These are worthwhile sites that enable users to find information useful for diagnostics, treatment recommendations, and various interventions quickly and efficiently. IDEA 97 (P.L.105-17) law and regulations are found at www.ideapartnerships.org. Education law can be found at www.bazelon.org. Congress and Federal Register information is available at www.thomas.loc.gov.

Other Web Features

Listservs are another service on the Internet. On these sites individuals sign up to receive regular e-mail messages on a specific topic or "thread." Any topic is available and can be found by search engines. The National Association of School Psychologists (NASP) has many Listservs that individuals may join. Listservs are not immediately interactive like a chat room, but an individual can respond to a posting, and everyone can see the response. Some Listservs can generate hundreds of e-mail a day on an active site. Some Listservs offer a digest format so you get all the messages in one e-mail on a regular basis and can read them at your leisure. Active Listservs can produce volumes of e-mail. Be sure to understand how to subscribe and unsubscribe for each one.

Newsgroups, similar to Listservs, are areas where any topic can be accessed. A popular newsgroup site is www.usenet.com, which has hundreds of listings about any topic imaginable. Users sign up and receive the postings through their e-mail service. Some newsgroups now charge fees for access.

The Global School Psychology Network, www.dac.neu.edu/cp/consult, offers access to consultation and peer-to-peer support. This is an innovation to connect school psychologists through the Internet. Distance learning allows individuals to take courses for college credit or continuing professional development, and it is exploding in popularity and usage across the world. Universities are offering college degrees through the Internet. There are many options for learning new techniques or intervention strategies. Many of these opportunities involve the capability to interact with faculty. Cybercounseling and Cyberlearning (Bloom & Walz, 2000) illustrate the potential for the future in using the Internet as a mental health learning tool (www.cybercounsel.uncg.edu). An advanced configured computer will likely be necessary to fully take advantage of these distance learning offerings (Alterkruse & Brew, 2000).

ETHICS AND TECHNOLOGY

Both NASP (National Association of School Psychologists, 2000) and APA (American Psychological Association, 1992) have ethical standards concerning the use of technology. APA also has the *Guidelines for*

Computer-Based Tests and Interpretations (1986) along with *Record Keeping Guidelines* (American Psychological Association, 1993) and *Services by Telephone, Teleconferencing, and the Internet: A Statement by the Ethics Committee of the American Psychological Association* (American Psychological Association Ethics Committee, 1995). The *Standards for Educational and Psychological Testing* (American Educational Research Testing, 1999) includes guidance and cautions about the use of computers in assessment. A book on computer ethics has been written by Johnson (1995). Technology is advancing at such a rapid rate that the reliance on technology has become a significant legal and ethical issue for school psychologists. Papers, books, and monographs on ethics and guidelines are typically out of date by the time they are printed.

McMinn, Buchanan, Ellens, and Ryan (1999) surveyed 1,000 APA members on their technology awareness and practices as related to ethical practice, and they included areas such as the use of telephones, faxes, and computer storage of data. They pointed out concerns about data loss and storage, confidentiality, computerized reports, and technology failure (e.g., the destruction of the computer's hard drive, a floppy disk does not work, phone message machines break down, computer virus). They posed the question about a computer hacker who breaks into a network and gains access to confidential files, and they asked psychologists if they thought this would be an ethical violation. Those concerns are neither clearly covered under existing ethical guidelines nor is it defined how far one must pursue these issues to still remain ethical.

Because psychological reports, computerized testing data results, and IEPs are stored on computer disks or networks, it is the best practice responsibility of the school psychologist to safeguard the confidential material. This can be done by password protection of files, not leaving data disks in the floppy drive, not sharing computers with others, and not e-mailing attached files to others. Ask your school's network director to have a secure space on the school's network where only the school psychologist's accounts are kept, password protected for each school psychologist. The rapid advances in e-mail, faxing, cell phones, etc., have made information instantly available. Data protection must be a priority. Most of what school psychologists do is considered confidential, but these new innovations of technology make information more open and available.

Other areas of potential problems include cell phone conversations that can be electronically monitored. Also, faxes can go to unsecured fax machines or to the wrong number. Confidential information should be sent to the intended individual, who is already standing by the fax machine. Having a fax sit where anyone can see is a potential for breach of confidentiality. An e-mail (which is not secure unless encrypted) may be sent to the wrong person or may have the wrong attachment with confidential information. It is possible to encrypt an e-mail so only the receiver can read it. Otherwise, e-mails are like postcards: anyone can potentially read them. Computers that are left on may have a report or testing data on the screen. A floppy disk left in a computer may have student data on it. These situations become particularly critical if the computer is stolen or hacked into by another individual or if disks are shared for report writing purposes. School psychologists must password-protect their computers and files so that no other individual can access them. Windows allows access to the computer to be blocked through its Access Password protection setup, yet even this may not protect from every circumstance.

An ethical nightmare for school psychologists may be to have their laptop computer stolen from their car or office with confidential information on it. Laptop theft is a chronic problem, and the school psychologist needs to safeguard all information by protecting the computer and its information. Locking cars and offices is an obvious recommendation, as is keeping the computer out of sight. Before a laptop or desktop computer is returned to the school district it should be purged of all confidential data and reports. Leaving this type of information on a computer would likely be considered an ethical and a possible legal issue.

Careful training of school personnel about issues of confidentiality is essential. If computers are used by multiple individuals or on school networks where others have access to any of its files, then there is a high potential for ethical or legal violations.

It is the school psychologist's ethical obligation to use the most current and accurate software available. "Per use" scoring software, such as Behavior Assessment System for Children (BASC), is updated by AGS regularly. Some cognitive tests are now available to administer directly on the computer, as are a variety of personality/behavioral rating software packages.

One final area of concern involves computer-generated reports from report and test scoring software. It is the school psychologist's obligation to ensure the accuracy of such information before it is used. Software packages are not perfect, and many of the first versions contain significant writing and scoring errors. Make sure to use the most current version. Report writers can provide inaccurate information, and scoring programs can be wrong. Report writer programs can also modify the school psychologist's writing style and intent. Just attaching printout information without interpreting it and relating it to the specific student's needs can be viewed as a potential ethical violation. No single data source should be used for diagnosis or placement decisions. Computer-generated regression formulas can be particularly troublesome without further information about the students' history and background.

Computerized IEPs may not be very "individual." Some software developers of these packages do not have individuality in mind. Widespread use of computer-generated IEPs makes them more cookie cutter than individualized. These issues all have the potential to create significant legal or ethical dilemmas for the school psychologist. An alternative is to use any word processing program and save various small files of typical text and explanations of the basic tests often used, and this is still keeping the spirit of the individual child yet will save time typing. Making a template or boilerplate of the specific test and student performance description areas can be done by using any word processor. The tests, results, and descriptions can be updated and modified as new instruments come out rather than having to replace the report writer software package.

All reports, interpretive results, and student files need to be password protected. Careful consideration of confidentiality and protection of the student's identity and records are ethically required. Owing to rapidly changing technology, new ethical and legal issues will continue to surface. School psychologists are required to keep current in all legal and ethical domains, and technology is a very important one.

THE FUTURE OF TECHNOLOGY AND SCHOOL PSYCHOLOGISTS

School psychologists must make a commitment to learn more about technology and its uses for themselves, educators, students, and parents. The "knowledge age" is quickly replacing the "industrial age." The future of technology holds much to help school psychologists perform at a higher level. Because of its importance, "technology" was added to NASP's Blueprint II as one of 11 domains that encompass training and practice (National Association of School Psychologists, 2000).

An expansive use of technology affecting school psychology practice will be "telehealth." This is defined as "the use of telecommunications and information technology to provide access to health assessment, intervention, consultation, supervision, education, and information across distance." (Nichelson, as cited in Reed, McLaughlin, & Milholland, 2000) The Global School Network is an example of this type of service. Rural areas will benefit most from such technology, but with it come the problems of legal and ethical transmission of information and data. The Global School Network has taken appropriate steps to deal with these issues. Telehealth is using video and/or audio technology to teach, supervise, and consult about patient care in the health field, particularly in hard-to-reach locations. Currently, the medical community is struggling with these complex issues, and psychology and education will, too.

Technology is changing as this chapter is being written. Electronic books are being marketed. Global Positioning Devices (which enable us to find where we are within 1 meter from any place on earth) are now under $200. Music is now in a sound chip, not on a CD. Computer games are as realistic as life. Wireless e-mail and Internet services are available in a palm-size computer, meaning no connections. Houses are computer monitored for heat/air conditioning, lights, conservation. Devices are available to perform extraordinary medical procedures that are technology based. The first artificial heart has been implanted. Functional artificial eyes and ears are within possibility. Voice-activated devices are available. The list appears to be endless, only constrained by imagination.

Projecting Into the Future

What are the prospects for the future professionally? How many of the following possibilities will in fact become reality? Medically, instant diagnostic procedures and electronic devices to replace damaged, worn out, or defective body parts will become commonplace. Computers will think and provide feedback when asked for answers. Artificial Intelligence (AI) will provide technology, allowing for interactive assessment with a computer. Virtual reality sites, long known for interactive game playing, will allow real-time visual and auditory counseling and assessment directly affecting school psychology practice. (Several software and hardware devices have already been developed for treating phobias with virtual reality.) On-line or computer based assessments and mental health counseling will be accessible to all. (Vocational assessment (PAR's Self-Directed Search) and personality assessment are already available on line.)

Continuing professional development and supervision will be done by Internet networks. Software will respond to voice activation, eliminating keyboards. Instant interventions will be available through massive databases. Students will need school psychologists to assess what is the best technology learning method for them. Students' desks will be computerized and on-line all the time. Teachers will be able to diagnose and correct student's work quickly and accurately. Parents and educators will want assistance in helping their children learn more efficiently with technology. School psychologists will need to provide the research base for "effective technological education."

All technological devices will be small and portable. There will be no test kits as known now, no bulky daily appointment books, no traveling long distances to assess someone, and no reports to type. Students will sit in front of computers to talk to psychologists or to take a test. Their activity will be monitored by a small camera or matching computer screen. All information will be available on any topic instantly. Few, if any, wires will connect devices because of wireless technology. It is planned that cell phones will be the contact with the e-world with e-mail, Internet services, appointments, video/photo output, plus phone contact. Computers will be all hand held and voice activated, possibly carried as a wrist watch.

These are possibilities. Some may not come to pass. Surely, others not yet imagined will become reality. Psychologists need to stay up-to-date or risk being left behind.

It may be difficult for school psychology training programs to adjust to this new technology. Being computer or technologically illiterate could be a handicapping condition. Most students today have more knowledge of technology than those who instruct them. The availability of technological advances will break out into the have and have nots, a significant issue for education.

The technology revolution has already changed how psychologists work, gather information, relate to others, and are educated. It is a massive challenge for educators to use this technology but not abuse it. School psychologists can play an important part in this revolution, but they will have to think outside the kit to accomplish this.

Trends in the History of School Psychology in the United States

Thomas K. Fagan
University of Memphis

OVERVIEW

This chapter is an update of that appearing in the last edition of *Best Practices*.. This chapter is not a chronological or topical treatise about the history of school psychology such as those appearing in Fagan and Warden (1996), Fagan and Wise (2000), and French (1990). Instead, this chapter expands upon previous work by providing brief descriptions of trends in selected aspects of the history of school psychology over the past century. Historical trend analyses, revealing the stability of some professional developments and the changeability of others, help us understand questions about our present by reflecting on our past. For example, is organizational growth since 1970 unprecedented? Is the literature of school psychology more diverse than in earlier times? Is the practice of school psychology different than it was 50 years ago? Have school psychologists always had children as their primary clients? These and other questions are addressed in this chapter. The discussion is not intended to be comprehensive but rather to provide an overview of some important trends in school psychology, and references for further study.

NUMBER OF SCHOOL PSYCHOLOGISTS

The earliest survey of psychological practitioners serving school settings was undertaken in 1913, and identified only 115 people. Growth in the number of school psychologists was gradual but persistent, and by 1950 there were about 1,000. The post-World War II baby boom, with its growth in school attendance, and the enactment of comprehensive special education laws entailing mandatory psychological services, were dominant forces affecting the rapid growth of practitioners observed after 1950. By 1970 the field had about 5,000 practitioners; current estimates range from 25,000 to 30,000. In recent years, growth can also be attributed to the expansion of settings in which school psychological services are delivered. Estimates of the size of the work force usually include trainers and state government personnel as well as practitioners. However, trainers comprise a very small proportion of the work force, perhaps 3–5%; and government personnel such as state consultants account for less than 1%. The size of the work force at different times is estimated as follows·

1920: 200
1940: 500
1950: 1,000
1960: 3,000
1965: 4,000
1970: 5,000
1975: 8,000
1980: 10,000
1985: 15,000
1990: 22,000
2000: 25,000–30,000

Despite several studies and estimates, no definitive count of the number of school psychologists has been accomplished. Even the term "school psychologist" has eluded consistent definition—adding to problems of whom to count and with whom past and future comparisons should be made. Recent estimates are more accurate than early estimates, but precision is still lacking. Despite problems of accuracy, the trend in upward growth has been significant. Continued growth is expected in the future, but not of the magnitude witnessed in the past 30 years. The number of school psychologists will probably not exceed 30,000–35,000 by 2015. Despite continued growth, the personnel shortages of the 1990s are likely to persist. There has never been a time when school psychologists suffered serious unemployment, and for most of the past century the demand has been greater than the supply of practitioners.

GENDER TRENDS

Public school teaching was a male-dominated field early in the history of American education, but has been dominated by women for more than a century, ranging from 86% (1919–1920) to approximately 70% in recent years. Throughout the twentieth century school psychologists were drawn in large numbers from the ranks of teachers. Even in recent years many school psychologists hold teaching credentials and have teaching experience. Although early survey data are not available, it is known that several women were among the early practitioners of school psychology (e.g., Norma Cutts, Gertrude Hildreth, Leta Hollingworth, Helen Thompson Woolley); that women held several prominent district-level administrative positions in school psychology (e.g., in Chicago, Cincinnati, Cleveland, Detroit), state department of education positions (e.g., New York, Wisconsin), and university positions (e.g., Columbia, Purdue); and comprised one-fourth of the Thayer Conference participants (French, 1988). Division 16-APA data indicated that women accounted for more than 60% of the membership and elected leadership in 1949, and 54% of its 600 members in 1956–1957. The figures appear to have declined to less than 50% by the 1960s, a period when men gained proportionally in leadership positions (Hagin, 1993). A more representative survey by Farling and Hoedt (1971) found an overall female representation of 40%, including 35% of the American Psychological Association (APA) member respondents and 47% of the National Association of School Psychologists (NASP) member respondents. A 1976 survey reported female representation of 45% (Ramage, 1979). By 1982 a NASP survey found women comprising 58% of the membership, and just 3 years later this had grown to 61% of the membership. Surveys in the early 1990s placed the membership representation of women at 65%, and more recently at 70% or more.

Given the representativeness among school psychologists of NASP's membership, the data suggest a substantial increase of females in the field in the past 20 years. The proportion of women in school psychology appears to have varied across the century, from perhaps 30% at some point early in the century to 50% or more during the period 1940–1960, perhaps experiencing a brief proportional decline in the 1960s and 1970s, and then rising to its present high of about 70–75%.

Referring to changes in gender as "the clearest changes in school psychology during the past two decades," Reschly (2000, p. 508) reviewed data on female representation by types of positions held. Female representation was 80% among graduate students in school psychology, 70% among practitioners, and about even with males among training program faculty.

Women's representation among the elected leadership of NASP improved from one-third to two-thirds of the positions during the period 1970–1993, but receded to about 55% in the past several years, in part due to the elimination of elected regional directors. A less discernible trend appears in the data for Division 16's elected leadership, though women held half or more of the positions on several occasions (Fagan, 1993b) and no less than half since 1996. Though regional variations likely exist, there are probably few states where men are in the majority. Despite their proportional advantage, a woman did not serve as editor of a school psychology journal until 1996 when Patti Harrison was appointed to the *School Psychology Review* (vol. 25, no. 1), followed in 1999 by LeAdelle Phelps to *Psychology in the Schools* (vol. 36, no. 3), and in 2001 by Susan Sheridan to *School Psychology Review* (vol. 30, no. 1). Several women have served in associate editorship positions.

The author considers the increase of women in school psychology to be among the more predictable and significant influences on the field for several decades. The proportion of women in school psychology may rise to as high as 80%. Although men have often held leadership positions in the past 30 years, the trend could change dramatically at all levels including state and national associations, academia, editorships, and state education agencies. With increased female presence in the leadership, the future of school psychology will be influenced by their efforts even more than in the past. The trend could be attenuated by recruiting more men into the field and/or by men continuing to be disproportionately successful in obtaining leadership roles. For example, 6 of the 12 most recent NASP presidents have been men.

SERVICE RATIOS

The ratio of school psychologists to children served—the service ratio—has been reported many times in our history. The ratio improved from 1:60,000 in 1934, to 1:36,000 in 1950, to 1:10,500 in 1966, to 1:4,800 in 1974, to 1:2,100 in 1986 (Fagan, 1988). In large and urban school districts the median ratio has improved from 1:18,500 in 1950, to 1:9,000 in 1966, to 1:2,000 in 1991 (Fagan & Schicke, 1994). These figures are consistent with Reschly and Connolly's (1990) report that the ratio for rural school psychologists (1:2,184) was not significantly different from that of urban (1:1,931) or suburban (1:1,892) school psychologists. Practitioners in combined settings (e.g., rural and urban) had significantly worse ratios (1:2,283). According to Reschly (2000), the national mean and median ratios are 1:1,930 and 1:1,750, respectively. Overall, the trend throughout the century has been improved ratios in various settings. Gradual improvements are anticipated for the future, but the NASP (National Association of School Psychologists, 2000) recommended ratio of 1:1,000 will remain an elusive goal.

PRACTICE SETTINGS

School psychologists have worked in several settings throughout history, although their primary identification has been with public and private schools. In the early decades of practice (1890–1920) they also worked in clinics and research bureaus affiliated with charitable agencies, juvenile courts, colleges and universities, and medical settings. Data by setting do not exist, but it is possible that nonschool-setting practitioners outnumbered school-based practitioners in the early years. Prominent early "school psychologists" such as Lightner Witmer and Arnold Gesell worked in the schools but from external agencies. This pattern probably changed in the 1920's, and may be the most significant event in school psychology in the twentieth century (Fagan, 2001).

Division 16-APA (School Psychology) was founded in 1945 and was originally intended for school-based practitioners, not practitioners in other settings. The Division's restrictiveness reflected a conceptualization of school psychology as applied clinical and/or educational psychology, with the school being the primary employment setting. A 1960 Division 16-APA survey found that among 233 respondents, 12 (5%) were from private schools, 11 (5%) from state school systems, 42 (18%) from county school systems, and 168 (72%) from city schools (Results of Questionnaire, 1960).

Setting expansion has been more noticeable since 1980, following a rapid growth of practitioners and increased interest in nonschool and independent practice. The shifting interest appears related to opportunities encouraged by federal legislation for the disabled (e.g., second opinion evaluations), the rapid growth of third-party insurance reimbursements for psychologists, the success of other psychologists in the private sector, increased numbers of school psychologists holding the doctoral degree, and a general maturing of the field of school psychology. Recent survey data indicate the following percentage distribution of employment settings for school psychologists: public school settings (89%), private practice (3.6%), clinic/hospital/other (3.9%), college or university (2.9%), and institutional/residential (0.5%) (Reschly, 1998).

Throughout our history we have maintained school psychology's identity with school settings despite gradual increases in nonschool practice. What does the future hold? There will be an increase in both the number of practice settings and the percent of school psychologists serving nonschool settings, but the schools will continue to be the dominant employment setting. Postsecondary educational setting practice will be more available, as will agency and private practice. The expansion of practice settings depends on the growth in the percent of practitioners holding the doctoral degree, and on the influence of managed care programs on private and clinic practice.

CLIENTELE

The issue of clienthood is complex, but most agree that children and their parents or guardians are the primary clients of school psychologists. School psychologists came into practice in order to directly serve children while working less directly with their teachers and parents. This primary client relationship with school-aged children has been maintained throughout our history. Surveys of practice, research studies on assessment and intervention, and other descriptive reports consistently reveal that school-age children have been the most common clients of the school psychologist. However, growing provision of consultation increases the extent to which teachers and parents are the primary service recipients and clients. School-age children will continue to be the most common direct service recipients, as well as the primary target of indirect services delivered through other recipients. Although the definition of "school-age" has expanded in recent decades to include ages 3–21, some school psychologists provide services to persons outside this age range.

PRACTITIONER SALARIES

Although salary data are practically nonexistent for the first half of the twentieth century, trends can be inferred from archival sources, from limited surveys conducted by state and national associations between 1940 and 1970, and from more comprehensive recent surveys. For example, when the Chicago Public School's Department of Scientific Pedagogy and Child Study was founded in 1899, its Director was paid $2,000/year and his assistant was paid $100/month ($1,200/yr) (Slater, 1980). Between 1915 and 1919, Arnold Gesell was paid $2,000 for his half-time, 9-month position with the state of Connecticut and he was reimbursed for travel, meals, postage, and telephone expenses. Archival sources also reveal that Gertrude Hildreth was paid $1,850 for her full-time, 9-month position in "mental testing" with the Okmulgee, Oklahoma, public schools in 1921. I suspect that the range of salaries in the period 1890–1930 was from $1,000 to $4,000 for full-time practitioners, and that a typical figure was probably $2,000 or less. Among the earliest known surveys is the 1939 state of New York survey (based only on the eight districts having a salary schedule), which found that "the range reported was from $1,400 to $4,000—the median being about $1,600 to $2,800" (Cornell, 1942, p. 25).

The 1954 Thayer Conference survey identified an overall salary range of $3,000–$15,000, with minimum salaries ranging from $3,000 to $4,600 and maximum salaries ranging from $3,600 to $15,000. Benefits and transportation allowances were mentioned (Cutts, 1955). A 1960 Division 16-APA survey ($N = 67$) revealed a median salary in the range of $7,000–$7,999. More than half (55%) were paid $7,000–$8,999. One-third to one-half of all respondents were given full expenses and time for attending professional growth meetings, and an additional one-third received partial expenses (Results of Questionnaire, 1960).

A reworking of the Farling and Hoedt (1971) survey data yielded a median salary in the range of $12,000–$14,999. (The original results (which totaled only 70%) reflected percentages based on the total sample of survey respondents and not just those who answered this question. The percentages were recomputed to reflect a distribution based only on the 70% who had responded (i.e., for a $N = 2{,}197$ instead of 3,138).) Regional data suggested higher salaries in the northeast and west than in the midwest and south (p. 75). The overall upper salary range was significantly greater than the 1960 Division 16 survey, with 84% reporting salaries of $10,000 or more compared to only 8% in the earlier survey. A 1976 survey of Division 16-APA and NASP members revealed the median salary to be in the range of $16,000–$18,999 (Ramage, 1979).

Surveys of the NASP membership reported in its 1982 and 1985 membership directories found the median salary in the range of $22,000–$24,000 and $25,000–$27,000, respectively. An independent survey of practitioners (Smith, 1984) revealed a median salary range of $20,000–$24,999. A 1990 survey of a random sample of NASP members ($N = 1{,}781$) indicated that the median salary was in the range of $35,001–$40,000 (Graden & Curtis, 1991). Reschly and Wilson (1995) reported a median income of $35,800 for practitioners and $44,500 for academicians, but the academicians had a median age six years older. Finally, on the basis of NASP's 1999 membership renewal data ($N = 13{,}813$), Thomas (1999) reported median and average practitioner salaries of $48,000 and $49,089, respectively.

Salaries have increased sharply in the past 30 years following small but persistent increases in the previous 50 years. The large recent increases are reflected in the 1990 data suggesting that 40% of NASP members had salaries of $40,000 or above compared to just 8% 5 years earlier. By 1999, 64% reported salaries of $40,000 or more. Sampling methods and the impact of rapid membership increases associated with NASP's system of national certification might partially explain discrepancies in surveys from 1985 to 1999. In the past decade, NASP membership has grown about 42% (Fagan & Bose, 2000), and the recessionary concerns of the early 1990s were followed by a strong economy.

Salaries by gender have seldom been reported, though a survey by Hall (1949) mentioned that one city had a differential between the salaries paid men and women psychologists; Smith's (1984) data suggest higher salaries for males, but this may have been a result of slightly greater levels of experience and degree attainment (see Table 2, p. 801). Teacher salary schedules, with some adjustments for psychological personnel, were reported in early and more recent surveys. No doubt, benefits also have improved in recent decades in comparison to the first half of the century. Salaries and benefits have improved considerably in the past several decades while the proportion of school psychologists who are women has increased substantially. Thus, the increased presence of women has not been associated with salary or benefits changes by gender.

PREPARATION PROGRAMS

The earliest programs were designed to prepare "clinical" practitioners to provide services in the schools (Fagan, 1999). The programs were not titled specifically "school psychology" until the 1920s, when the first so-titled program was established at New York University. The second formal program appears to be the doctoral program founded at Pennsylvania State University in the late 1930s. By the time of the 1954 Thayer Conference there were 18 programs, including 5 at the doctoral level (Cutts, 1955). Institutions offering training in school psychology grew from 28 in 1954, to 79 in 1964, to 147 in 1974, to 211 in 1984 (Fagan, 1986b). The 1989 edition of the NASP training program directory identified 231 program institutions while the 1998 edition identified 218 program institutions. A leveling of growth in the number of training program institutions has occurred since the early 1980s. Future growth in the number of participating institutions will remain modest. The number is unlikely to exceed 250 and conceivably will decrease. The most predictable increase is in the number of institutions offering a doctoral program in school psychology. Although few in number at present, we can anticipate growth in the number of programs offered by free-standing professional schools of psychology, and by distance learning institutions.

CHARACTERISTICS OF PREPARATION

In the early part of the century, school psychology programs were oriented toward clinical psychology, educational psychology, or a combination thereof. Even the earliest training programs created specifically for school psychologists tended to take these orientations. Perhaps the earliest unambiguous joint orientation of educational and clinical psychology was the University of Illinois program, founded in 1951. Programs have been developed in both education and psychology administrative units with few apparent differences (Fagan & Wise, 2000; Reschly & McMaster-Byer, 1991).

The content of training programs was largely unregulated until the 1960s in what might be called a long period of "diversity of necessity" in which training emerged from programs designed for a variety of educational and psychological personnel. Many of the programs established in that era included traditional core psychology or core education courses with specialty training, including psychoeducational evaluation but with limited emphases on interventions. With the establishment of APA and NCATE/NASP accreditation, the profession entered a period of "restriction for identity" in which very specific standards for preparation were developed to give school psychology training its own identity. Accrediting and credentialing standards also have brought about broader and more specific content in programs. The standards have significantly raised the expectations for entry-level training and have broadened preparation to include various types of assessment and intervention. The current entry-level expectation of the specialist degree or its equivalent is more than twice the expectation published in the original NASP training guidelines of the early 1970s.

However, in raising the expectations to meet job demands and establish a separate training identity in school psychology, nondoctoral programs have been forced to become highly prescriptive. Doctoral programs have tended to follow the broader scientist-practitioner or professional models of preparation.

The past several decades have seen an improved balance of psychology- and education-related content. Very noticeable changes have been the expansion of field experience requirements, including practica and internships, and the infusion of faculty specifically prepared as school psychologists. While a sharp increase in training standards is not expected in the foreseeable future, an upward trend will continue. This may appear first at the doctoral level, where national forces are driving accrediting and credentialing toward the post-doctoral level. Nondoctoral standards are expected to remain similar in total length of preparation (e.g., 60–66 semester hours), though content shifts are anticipated to accommodate concerns in certain areas (e.g., technology and crisis intervention). We should encourage a future of "diversity for maturity," where many forms of preparation will be available in order to better prepare persons for practice in a future of increasing diversity of settings and clients.

CREDENTIALING

Although the New York City Board of Education had provisions for examining and approving school psychological personnel in the 1920s, the earliest state education agency credentials for school psychologists were granted by New York and Pennsylvania in the mid-1930s. Licensing for nonschool practice by state boards of examiners in psychology was initiated in 1945 (Connecticut). By 1960, 15 states licensed psychologists, and all states did so by 1977 (Missouri was the final state). State board of education certification was available in at least 7 states by 1946, 11 states by 1949, 20 states and the District of Columbia by the time of the Thayer Conference in 1954, 24 states (including D.C.) by 1960, 37 states by 1965, 42 states (including D.C.) by 1973, and all states (including D.C.) by 1977 (Brown, Horn, & Lindstrom, 1980; Pryzwansky, 1993). A historical analysis of specific changes in credentialing requirements over the past 65 years has not been undertaken and is beyond the scope of this chapter. However, a discernible trend has appeared requiring greater amounts of graduate education and supervised field experiences, and program approval or accreditation. Teaching credentials and/or experience were not required in the original certification in New York and Pennsylvania, and such requirements have declined from 12 of the 20 states certifying school psychologists at the time of the Thayer Conference to only a few states at present. A current analysis of credentialing requirements appears in Curtis, Hunley, and Prus (1998).

LITERATURE

Until the appearance of the first issue of the *Journal of School Psychology* in 1963, the field had no direct journal outlet for its research and professional literature. Before then, the field relied upon an assortment of journals in psychology and education, including *American Journal of Psychology*, *American Psychologist*, *Journal of Educational Psychology*, *Journal of Consulting Psychology* (now *Journal of Consulting & Clinical Psychology*), *Pedagogical Seminary* (now *Journal of Genetic Psychology*), *Psychological Bulletin*, *Psychological Clinic*, and *Psychological Review* (Fagan, 1986a). Attending the growth of school psychologists since 1960, the growth of school psychology journals was rapid and included the publication of *Psychology in the Schools* in 1964, *School Psychology Digest* (now *School Psychology Review*) in 1972, and *Professional School Psychology* (now *School Psychology Quarterly*) in 1986. Related journals, including those mentioned above, have continued to be important, including *Exceptional Children*, *Journal of Learning Disabilities*, *Journal of Psychoeducational Assessement*, *Professional Psychology: Research & Practice*, and *Special Services in the Schools*, as well as a growing number of journals on specific techniques or disorders. North American school psychologists also subscribe to the *Canadian Journal of School Psychology* and *School Psychology International*, founded in 1985 and 1979, respectively. A few state school psychology associations have published a journal including the *New Jersey Journal of School Psychology* in the 1980s and *The California School Psychologist* in 1996. It is of historical importance to note that the *Journal of School Psychology* was originally published for Ohio school psychologists by the Ohio Department of Education.

National newsletters in the United States specific to school psychology date to the Division of School Psychology's newsletter in 1947 (titled *The School Psychologist* since 1966) and NASP's newsletter in 1969 (titled *Communiqué* since 1972). An international newsletter, *World-Go-Round*, appearing since 1973 predated the founding of the International School Psychology Association in 1982. Newsletters for trainers of school psychologists include *The School Psych Scoop* in 1972 (titled *Trainers' Forum* since 1981) and the Council of Directors of School Psychology Programs' *CDSPP Newsletter* in 1982 (titled *CDSPP Press* since 1990). State association newsletters are common and usually date to the earliest years of these groups (see Fagan, Hensley, & Delugach, 1986). Lesser known newsletters have included those by NASP special interest groups and by other organizations such as the Society for the Study of School Psychology.

Trends in the publication of books about school psychology appear in Fagan (1986a), French (1986), and Whelan and Carlson (1986). These surveys identify the chronological order and significant content changes of books in the field. The earliest book specifically about school psychological services was published by Gertrude Hildreth in 1930 (*Psychological Service for School Problems*). A period followed in which few books were published, including the Thayer Conference proceedings, and then a surge of books appeared beginning in the 1960s. The number and diversity of books published follow the growth pattern for journals during the period 1960 to present. Despite a paucity of school psychology books and journals prior to the 1960s, the field has been served by many literary sources throughout the century (Fagan, Delugach, Mellon, & Schlitt, 1985; Fagan & Warden, 1996; Fagan & Wise, 2000).

ORGANIZATIONS

Organizational entities exclusively serving school psychologists originated with the Division of School Psychologists of the APA (Division 16-APA) established in 1944–1945, which evolved from the Educational Section of the American Association of Applied Psychologists (AAAP), established in 1937. Prior to the existence of these organizations, school psychologists appear to have been members of various groups, including the American Psychological Association (founded in 1892) and its off-shoot the American Association of Clinical Psychologists (founded in 1917), which became the APA Section of Clinical Psychology in 1919, and the Association of Consulting Psychologists (founded in 1930), which evolved into the AAAP. Although some school psychologists were members of the National Education Association, throughout the first half-century most did not belong to any professional organization for psychologists (Fagan, 1993a). Division 16-APA was the only national-level organization for school psychologists until the founding of NASP in 1969. For the past 33 years, both Division 16 and NASP have served as national representatives of school psychology's interests. The founding of the American Psychological Society in 1988 and the American Association of Applied and Preventive Psychology in 1990 represent increasing organizational diversity. Their effect on school psychology remains to be seen, and only a small percentage of school psychologists have become members. Recent information about the history and activities of NASP and Division 16 can be obtained in Fagan, Gorin, and Tharinger (2000). Similar information on the International School Psychology Association appears in Oakland (2000) and the Canadian Association of School Psychologists in Saklofske et al. (2000).

The earliest state association for school psychologists appears to be that founded in Ohio in 1943. The growth of such groups was gradual, and by 1969 there were only 17 state associations, several of which were sections of their respective state psychological associations and affiliates of the APA. Growth in the number of states having separate school psychology associations that affiliated with NASP was rapid in the 1970s and 1980s (Fagan, Hensley, & Delugach, 1986). Every state has an association for school psychologists, and in some states there is both a division for school psychologists within the APA-affiliated state psychology association and a separate NASP-affiliated association. The situation is similar, though more complicated, in Canada and its provinces (see the special issue of *Canadian Journal of School Psychology*, vol. 16, no. 2).

ROLES AND FUNCTIONS

Twentieth-century American education has been characterized by increased segmentation and sorting of children, presumably so that education can intervene in children's lives in more meaningful ways. The sorting function of education has a long tradition dating to the acceptance of compulsory schooling and the employment of experts, including psychologists, to assist in the segmentation of students. The sorting for programmatic interventions has ranged from school lunch programs, Title I, vocational education, advanced placement, or honors classes to several categories of special education. It is common for large school systems today to have numerous specialized programs operating concurrently and overlapping in regular and special education settings.

As part of this growing bureaucratic process, school psychologists have served two primary functions (Fagan & Wise, 2000). The first has been a role of sorter, in which the most visible function has been the psychoeducational assessment of children for placement in special education programs. In earlier decades, this role was predominantly psychometric, although the conceptualization and practice of assessment has broadened in recent decades as a result of legislative and litigational initiatives and shifting problem-solving strategies. School psychologists now work as members of service teams in which a more comprehensive approach to assessment is taken.

A second role, that of repairer, has engaged school psychologists in individual and group interventions. In earlier decades this often involved academic remediation and counseling. More intensive interventions, such as psychotherapy, were often restricted, prohibited, or considered too time consuming or too costly to be done by district-based practitioners. This has changed in the past 35 years as a result of broader training, supervised internships, greater availability of school-based practitioners, and a gradual shifting of administrators' thinking in the direction of serving children's mental health as well as academic needs.

A third role, consultation, could be considered a special case of the repairer role, but it has received so much attention since the 1960s that often it is considered a separate role. There are many instances of consulting in the early literature of our field, but the in-depth consultation characteristic of recent times was only occasionally practiced and seldom researched. All school psychologists occasionally consult with others, but that does not mean they are engaged in consultation. To effectively function in the consultant role, a practitioner now requires specialized preparation and experience.

A fourth role is that of engineer, in which the practitioner works with overall service delivery schemes. This extension of the consultation role to systems analysis and development focuses its assessment, interventions, and preventive strategies at systemic needs, not the needs of individual children, parents, or educators. Until recent times, this role was rarely performed by school psychologists.

Many school psychologists enjoy broader roles and functions than others did in earlier decades. However, most continue to practice the two traditional roles of sorter and repairer, with attendant functions of traditional psychoeducational assessment and one-to-one or group interventions with children (Reschly, 2000). The similarity of roles over time gives a false impression that little has changed in the practice of school psychology. The technical quality and knowledge about assessment and intervention functions (e.g., cognitive and achievement tests, behavior modification, or behavioral consultation) have strengthened the roles of school psychologists. Perhaps the most striking changes have occurred in the context of practice. Just 30 years ago most school psychologists worked without requirements for parent/guardian permission, multidisciplinary teams, annual reviews and Individual Educational Plans, and least restrictive environment placements. The category of learning disability, now the largest area of exceptionality, was just gaining official recognition. Federal laws related to the education of the handicapped (now known as IDEA) were nonexistent, and most special education services were provided in segregated programs. Among the more frequently given tests were the WISC, Stanford-Binet (1960 edition), Illinois Test of Psycholinguistic Abilities, Frostig Developmental Test of Visual Perception, and the Bender Visual-Motor Gestalt Test. The school psychologist typically held a Master's degree, including a practicum, and little or no internship experience. In some settings the school psychologist served in a dual capacity as psychoeducational assessment specialist and coordinator of special education. The school psychologist was a one-person multidisciplinary team. Although some aspects of role and function have persisted, there has been considerable change in our field.

PROBLEM-SOLVING STRATEGIES

Although their approach to the task has varied over the century, school psychologists have been employed to help alleviate the problems of children and their schooling. This discussion of problem-solving approaches focuses only on the sorter and repairer roles—that is, the traditional child study approach to services—and not on systems level and preventive approaches. Early descriptions of practice reveal a problem-solving strategy that focused almost exclusively on the individual child. This strategy sought solutions to children's school problems by studying their identifiable skills and the presumed underlying abilities, traits, or personality characteristics. Problems were considered to rest with the skills and characteristics associated with the child, and the solutions rested with their alteration. Diagnosis and intervention were child-centered. Assessment methods included questionnaires; interviews of the child, parent, or teacher; tests (both standardized and unstandardized, normed and unnormed); inspection of the child's work; school and health histories; and occasional classroom observations. The rapid acceptance of the Binet-Simon intelligence scales and standardized norm-based achievement tests was attributable to the apparent objectivity they brought to an assessment process fraught with varying opinions about classification and degrees of symptomatology. The new tests added scientific respectability to child study by quantifying the extent of a problem and contributing to greater objectivity in classification. Interventions included brief counseling, remediation of academic skills, and an expanding array of instructional and community-based programs in special education.

In part as a result of debates over nature and nurture, as well as the increasing influence of behavioral psychology, the modal problem-solving strategy of school psychologists gradually expanded to more often include the assessment and intervention of persons and factors beyond the individual child. The most obvious shift of focus was from the child to the parents and guardians. For example, for many years it was believed that certain child problems (e.g., autism) were etiologically linked to inadequate parenting (often construed to mean inadequate mothering in an era when societal consensus held that mothers were the primary child caretakers). The focus also expanded to classroom variables, including teacher characteristics and the characteristics of their teaching. As this strategy continued to expand, the notion of problem-solving assessment broadened to the concept of ecological assessment. The child continued to be the focus of study, but only in relation to the study of other variables in the child's environment and especially the child's unique interaction with this environment. Logically, the etiology of children's problems expanded as well. Failure was no longer viewed in terms of child variables but also in terms of other factors, separately or in combination with child variables (e.g., ineffective teaching with children having specific learning deficits).

The methodology continued to include standardized and unstandardized, normed, and unnormed tests. Also included were an array of measures, formal and informal, of peer relationships and sociograms, attitude toward school, parenting, classroom climate and teaching, socioeconomic status, and formalized observations of child and peer behaviors (e.g., event and time sampling). Interventions continued to include the earlier forms, though with greater sophistication in special education programs and diversified therapeutic techniques (e.g., client-centered, rational-emotive therapies, and behavior modification) applied to groups as well as to individuals. Problem solving was still focused on the child, although increasingly school psychologists relied upon indirect interventions such as teacher and parent consultation (see Kehle, Clark, & Jenson, 1993; Sandoval, 1993).

The ecological viewpoint (including reciprocal determinism), with its contention that variables external to the child are worthy of study and intervention, has strongly influenced school psychology for the past three decades (see e.g., Elliott & Witt, 1986; Sheridan & Gutkin, 2000). In recent years, the problem-solving task has shifted some of its focus back to the child in the form of directly measured observable skills and corresponding direct interventions. At least where the "high incidence" problems of children are concerned (e.g., learning disability, educable mental retardation, emotionally and behaviorally disturbed) the shift has been toward disavowing underpinning normative characteristics in favor of direct interventions in observable academic and social behaviors. A long-standing paradigm of assessing skills through underlying supportive characteristics (e.g., intelligence) has shifted to a paradigm of direct assessment of skills and direct remedial instruction irrespective of underlying abilities or traits. The current conceptualizations are identified with an "outcome education" orientation under various names including authentic-, curriculum-, performance-, and portfolio-based assessment. These are variations on earlier themes of criterion-based assessments that have been popular at different times in our history. Other shifts in problem solving have focused on parent and teacher effectiveness, and the child's family constellation. It is now common for school psychologists to consider family variables in both their diagnostic and intervention efforts, and systems have been developed for family assessment and therapy.

In summary, school psychologists have always been identified with one or more problem-solving strategies, the nature of which has shifted over time. Although it is easy to look back with disdain on the practices of earlier eras, earlier practices were influenced as much by broad societal ideologies of the period as by professionals' lofty aspirations. For example, the recent clamor of interest in the family has occurred after an era of governmental, societal, and professional alarm over family deterioration. There was less focus on the family in the 1950s, an era often viewed nostalgically as one of family strength. The irony points to our tendency to draw attention to phenomena for study after the fact. The shifting strategies toward child study are probably less on the cutting edge of practice than they are on the backside of educational and psychological research and on societal acceptance of the changing spheres of child influence. Another example can be seen in the current interest in risk assessment of children as a result of several incidences of school violence perpetrated by students since the early 1990s.

In retrospect, we observe stages of development in problem-solving approaches associated with a broadening recognition and acceptance of the spheres of influence on children. While clear-cut temporal or strategy demarcations cannot be specified, the expansion of spheres generally has been from child, to parents and teachers, to family and school, to community and society. Even though the stages overlap and continue to be observed in the varied practices of professional psychologists, comprehensive assessment and intervention practices have expanded accordingly. Contemporary thinking is conceptualized in the systemic analyses of Bronfenbrenner (1979) and their applications to children of disability (Seligman & Darling, 1997).

Critics of traditional school psychology contend that earlier practice was never based on a problem-solving model. However, all problem-solving models involve assessment and intervention. The traditional model identified the school psychologist primarily with assessment to determine eligibility for interventions most often provided by others via special classrooms and programs. Most traditional school psychologists were, and many still are, not effectively linked to the intervention side of problem solving. However, that does not mean the overall process is outside the realm of problem solving. Employing an assembly line approach to automobile making, instead of having each worker build the entire car, does not make the assembly line approach outside the realm of automobile making. Further, the shift from processing assessment to functional assessment does not mean that the former was outside the realm of a problem-solving model. What has changed is simply the nature of the assessments advocated and the involvement of the school psychologist throughout the assessment and intervention. Some advocates of the "new" problem-solving approaches have chosen to dissociate themselves from the earlier approaches to practice, preferring reform to transition in practice. However, even the current *zeitgeist* is historically linked to earlier approaches known as diagnostic teaching during Witmer's time, and precision teaching, directive teaching, and mastery learning in the last three decades. The recent shifts in problem-solving strategy could benefit services in the long run if they successfully draw greater attention to the importance of interventions and recognize the complementary relationship between child-centered and ecological assessment approaches, and normative-based and criterion-based measurement. The shift toward collaborative inclusion of parents and teachers as peers in the problem-solving process could also have positive implications. Finally, perhaps the school psychologist will earn a more balanced role than in the past, as "repairer" instead of "sorter" of children's problems. For discussions of possible future trends in school psychology see Oakland and Cunningham (1999), *Psychology in the Schools* (vol. 37, no. 1), *School Psychology Review* (vol. 29, no. 4), and Ysseldyke et. al (1997).

16 Best Practices in System-Level Change

Michael J. Curtis
University of South Florida
Stephanie A. Stollar
Southwest Ohio Special Education
Regional Resource Center

OVERVIEW

Consider several different situations that might very well confront school psychologists:

1. The School Improvement Team establishes a goal of collaborating with parents in promoting positive home-school approaches to discipline.
2. An elementary school wants to implement strategies for more effectively responding to the needs of a growing number of Limited English Proficiency (LEP) students.
3. The School Psychological Services Department is attempting to shift its service delivery model from an emphasis on test and place to one that emphasizes intervention-based problem-solving practices.
4. The district is reexamining policies and procedures in order to comply with the Individuals with Disabilities Education Act Amendments of 1997.

Each of these cases represents a system level issue and each situation is likely to impact school psychologists. On the other hand, in each situation, school psychologists with knowledge and skills in system-level consultation could facilitate change at the classroom, grade, building, or district level.

A number of major developments over the last few years necessitate the involvement and support of school-based professionals who are highly skilled in problem solving and who understand and can facilitate organizational change. Further, there is increasing interest among school psychologists and a growing demand among consumers for services that are based on an intervention-based problem-solving model. In addition, the Individuals with Disabilities Education Act Amendments of 1997 clearly emphasize the "outcomes" of services, ensuring meaningful educational progress for all students with disabilities (Yell, Drasgow, & Ford, 2000) rather than limiting the focus to procedural safeguards, the central trait that characterized prior special education legislation. These major developments require fundamental changes in the way school psychological services are conceptualized, organized, and delivered.

Although system-level change has not been among the services emphasized by many school psychologists, it is an area to which many school psychologists could bring valuable knowledge and expertise. The central foundation of psychology is the understanding of human behavior. A special strength of school psychology is understanding human behavior within the context of schools and educational institutions as they function in relationship to families and the larger community. In other words, school psychologists understand human behavior within the ecology of the school as part of a larger system. Attesting to the importance of expertise in systems change, standards recently adopted by the National Association of School Psychologists (NASP) for both training (National Association of School Psychologists, 2000b) and the provision of school psychological services (National Association of School Psychologists, 2000a) address preparation and practice in system-level influence and change.

BASIC CONSIDERATIONS

There are some circumstances in which a school psychologist might function in the role of a system-level change agent from outside the organization (e.g., the school psychologist would be employed for the specific purpose of delivering system-level consultation). However, in most cases, the school psychologist will be employed by the organization and system consultation will represent only one of a variety of direct and indirect professional service functions. In order to engage effectively in system-level consultation, school psychologists need to call upon three areas of expertise: (a) understanding human behavior from a social systems perspective, (b) ability to use collaborative planning and problem solving procedures, and (c) familiarity with principles for organizational change.

Schools as Social Systems

Although schools usually can be identified by their physical appearance, without students and the personnel who work there, they are very much like any other building. Bricks, mortar, steel beams, and glass do not tell you much about the character of a school. Regardless of physical structure, it is the people within who give it life. Because of its people, a school is a social system. Furthermore, no two schools are functionally alike because of the uniqueness of the individuals who inhabit and affect each of them.

UNDERSTANDING SYSTEMS

System-level intervention and organization development are founded in general systems theory. Initially, the application of systems theory was confined largely to military and industrial settings. The relevance of systems theory to the behavioral sciences did not emerge until the mid 1950s (Miller, 1955). The first systematic effort to use systems theory in schools as a framework for analyzing complex organizational problems and developing solutions did not begin until the early 1960s (Miles, 1963). Much of the early movement to study and improve schools as organizations was stimulated by the work of Schmuck and his colleagues (e.g., Schmuck & Miles, 1971; Schmuck, Runkel, Saturen, Martell, & Derr, 1972).

DEFINING A SYSTEM

It is important to clarify the meaning of the term "system." A system is an orderly combination of parts that interact to produce a desired outcome or product. An automobile engine is an example of a system. It consists of a number of specific parts that interact to produce power and motion. However, in contrast to a living system, an automobile engine is an example of an *inert* system (i.e., as long as the parts continue to function in the same way, the engine should continue to produce power in essentially the same way).

Because it is people who give schools their real meaning, schools are *living* systems. Living systems exist on a continuum beginning with individual cells within a human being and extending all the way to the entire population of the Earth. For the purposes of this chapter, however, a somewhat narrower spectrum is appropriate. For our purposes, *a system is the orderly combination of two or more individuals whose interaction is intended to produce a desired outcome.*

A school is a system because it consists of component parts (e.g., students, teachers, school psychologists, cafeteria workers, parent volunteers, principal) that are organized and interact for the purpose of producing a definable outcome: educated children. As is true of all systems, the school is also part of a larger system, the school district (in systems terminology, the larger system is referred to as a "suprasystem"). Individual classrooms, grade level teams of teachers, local school improvement committees, and intervention assistance teams are examples of inner systems within the school, or "subsystems." Each consists of component parts that interact for the purpose of attaining desired outcomes, and each exists within a larger system.

Reciprocal Influence. A critical feature that differentiates a living system from an inert system is its ability to interact with and to react to its environment, both internally and externally. Because of their capacity to interact with the environment, all living systems are "open systems." Each of the parts of a system influences all of the other parts, as well as the performance of the system as a whole. A change in one part of the system will cause change in other parts of the system. For example, if the building principal is replaced by a new principal, then that change is likely to affect classrooms, students, teachers, the school psychologist, cafeteria workers, and others. Although changes in one component of the system may tend to have more impact than would change in others because of the role played by that particular part (a principal versus one student), *each part*, regardless of role or size, influences the system as a whole to some degree. Also, circumstances may significantly alter the system more than normally would be expected (e.g., a tragedy involving one student that affects everyone in the school). Similarly, changes in the larger surrounding environment (the suprasystem) influence the system, as well as the components (subsystems) within. For example, the enactment of a new district policy on discipline would influence the individual school, as well as its teachers, students, and other personnel to varying degrees.

A systems perspective involves the ability to understand how the various component parts of a system, the system itself, and the surrounding system or environment influence one another. Bandura (1978) suggested viewing the individual child within a systems framework. From the systems or ecological perspective, the child is one element in a larger environment. The child influences and is influenced by various forces in the system of which s/he is a part.

The Capacity of the System to Solve Problems. One of the ways in which systems differ is the extent of their openness to environmental influences, both internal and external. Healthy systems, based on their identified goals, screen environmental information, accepting that which is important, rejecting that which is not, and responding in a manner that is appropriate for the information received. In other words, healthy systems demonstrate the capacity to analyze problems and to solve them in a manner that facilitates the attainment of their goals.

Of course, some systems lack the capacity to solve problems effectively. In some cases, they are not sufficiently open to accept important information. Or they may have been open at an earlier time, but because they did not have the ability to solve problems confronting them, they became closed, somewhat like the ostrich with its head in the sand. The inability to interact with influential forces, internally as well as externally, creates tremendous tension in closed systems. If the tension reaches a high enough level, a crisis occurs that causes some type of change in the system.

Rigidity Elementary School offers one illustration of a closed system. An increasing number of discipline problems are occurring on buses transporting students to and from the school. As a result, several parents have called the school to express their concerns. Initially, the principal tells the parents that these are isolated incidents and that such problems rarely occur. As the problems continue to increase, the principal has the receptionist screen his calls, telling parents that he is in a meeting and will return their calls later. However, the calls are never returned. Angry parents show up at the school, asking to see the principal, but he isn't available. Frustrated and fearful for their children, the parents show up and voice their anger at a meeting of the district board of education. Eventually, the principal is forced to respond to the parents' concerns or is replaced.

On the other end of the continuum, some systems are too open and are unable to screen environmental forces. They essentially accept all input and try to respond to everything, often with the same level of intensity. They are overwhelmed and operate in a constant state of crisis. Everything must be done immediately! Crisis Elementary School serves as an example of this type of system. In this case, every time a parent calls the school to express a concern the principal responds by writing a memorandum to the entire staff or creating a new policy that affects the entire school. As a result, the school is in a constant state of change. In such systems, because there is a lack of stability and continuity, it is exceedingly difficult to set goals, make plans to attain them, and monitor progress. In addition, the energy invested and the attention required to constantly respond to all forces, regardless of importance, is not available to address issues that should be a priority or to pursue the goals of the system.

The primary goal of system-level consultation is to increase the problem-solving capacity of the system so that it can deal with all problems more effectively. In this way, system-level consultation is exactly like one-to-one consultation. While the immediate objective in one-to-one consultation is to help the person requesting assistance solve the problem, the primary objectives are to help that person become more effective in solving similar problems in the future and to become a more effective problem solver in general. In system-level consultation, the system is the consultee. While the immediate goal is to help the system solve a specific problem, the primary goal is to facilitate the development of the system as an effective problem solver. In both cases, although involvement in consultation is likely to result in improved problem solving for the consultee(s), direct training in problem solving methods will result in greater and more immediate skill development (e.g., see Curtis & Metz, 1986; Zins & Ponti, 1996).

Collaborative Planning and Problem Solving

Collaboration serves as the foundation for system-level consultation. *For the purpose of consultation, whether one-to-one or system level, collaboration means two or more people working together, using systematic planning and problem-solving procedures, to achieve desired outcomes.*

The principles of collaborative planning and problem solving that apply to individual consultation are directly relevant to system-level consultation as well. In fact, collaborative one-to-one consultation and system-level consultation are directly parallel in almost every respect. Although we will not discuss one-to-one consultation skills in depth here, it would be helpful to note very briefly some of the fundamental characteristics of effective consultation.

INTERPERSONAL RELATIONSHIPS

Effective consultation is based on mutual respect, trust, and coordinate power status among the participants. The role of the system consultant is to facilitate the efforts of the group to achieve the goals that *the group* has decided upon, in a manner that *the group* chooses. Effective communication skills are essential for a consultant. The ability to listen, ask open-ended questions, paraphrase, and summarize and synthesize information, all within a nonjudgmental climate, are especially important. These skills take on added significance when attempting to facilitate change from *within* the system. Group members are often not very tolerant of a member whose behaviors tend to alter the coordinate power status among members (e.g., by giving unsolicited feedback to the group or to individual members).

PLANNING AND PROBLEM-SOLVING SKILLS

It is essential to remember that consultation is a problem-solving process and that attention to *both* interpersonal skills *and* problem-solving procedures are critical in determining success. Curtis and Van Wagener (1988) demonstrated that despite highly effective interpersonal skills, consultation was not effective in resolving student-related concerns when problem-solving procedures were not employed. Effectiveness in each area is necessary, but insufficient by itself.

Fundamental planning and problem-solving procedures are very similar, with the major difference being one of direction. Whereas planning is intended to achieve a desirable goal, problem solving is intended to alleviate an undesirable condition.

There are hundreds of articles and other works in which authors have discussed planning and/or problem solving. Many models have been proposed that apply such procedures in different ways and incorporate varying numbers of steps or stages. Bergan's (1977) four-step model has received a great deal of attention in the school psychology literature and a number of recent publications present detailed discussions of methods for using Bergan's model (e.g., Sheridan, Kratochwill, & Bergan, 1996). Although the number of steps may vary, most models reflect the inclusion of four major stages implicitly, if not explicitly:

1. Problem/Situation Analysis

2. Goal Identification

3. Strategy Development and Implementation

4. Evaluation

Regardless of the model chosen, effective consultation must include all four of these stages. However, it also should be noted that although such models typically describe a specific sequence of stages, actual problem solving during individual consultation often does not proceed in such a mechanical, lockstep manner. Rather, movement back and forth among the stages is common. Nevertheless, the general sequence of stages typically should occur as described and *all* stages must be included. For a comprehensive review of the consultation literature and a discussion of the core characteristics of different consultation models, including interpersonal relationships, as well as problem solving, the reader is referred to Gutkin and Curtis (1999).

Principles for Organizational Change

Since applications of system-level analysis and organization development to schools received little if any attention until the mid-1960s, the area remains relatively new. Yet, a considerable amount of organizational change research and conceptual literature regarding other social systems has been published. This work, when combined with the research and conceptual literature generated specific to educational settings, provides a very useful knowledge base to guide system-level consultation in schools. Recently, a number of researchers and authors, including Senge (e.g., see Senge, 1990; Senge, Kleiner, Roberts, Ross, & Smith, 1994) and Fullan (e.g., see Fullan, 1995, 1997; Fullan & Hargreaves, 1996) have made significant contributions to the organizational change literature.

BEST PRACTICES

Best practices in system-level consultation can be illustrated through an examination of key concepts and practices that are addressed in the organizational change literature. Furthermore, it is important to remember throughout the following discussion that system-level consultation is a problem-solving process and, therefore, directly parallels the steps of individual problem solving. Key concepts and principles for organizational change through systems consultation will be identified and discussed.

Planning for Change

A definition of organization development provides fundamental principles to guide the practice of system consultation. Although a number of definitions have been suggested, for our purposes *organization development is the planned and sustained effort to bring about system-level improvement through self-analytic and problem-solving methods.* System-level change must be planned and pursued in a systematic manner over time. It does not just happen. Furthermore, it is not an event or activity, but an on-going process that should never end. The definition presented above also emphasizes the critical point discussed earlier (i.e., the primary goal of system consultation is for the system to become more effective in solving all problems). Solving a specific, precipitating problem should be considered only a short-term goal. However, it typically is the precipitating problem that provides an opportunity to engage in a longer, sustained effort for system-level change. In this way, system consultation parallels individual consultation. A specific concern causes someone to seek assistance. But the resultant involvement in consultation is intended to increase the general problem-solving skills of the consultee, as well as to address the precipitating concern.

UNIQUENESS OF EACH SYSTEM

The same intervention would not be employed to address different concerns relating to different students. The intervention would have to fit the specific problem in each situation. Yet, in system consultation, there sometimes seems to be a tendency to use the same change strategies, regardless of the specific characteristics and needs of different systems.

System consultation is built upon careful analysis of the organization and the resulting plan that is designed to address the unique needs and characteristics of a particular system. Two types of procedures that are useful at this stage include *diagnostic evaluation* and *input evaluation.* Diagnostic evaluation is helpful for identifying the needs of the system through multiple sources. It might be conceptualized as a multifactored evaluation at the system level. Formal techniques such as surveys and questionnaires may be combined with informal measures such as interviews and observations to provide a complete understanding of the organization. Needs assessments are particularly useful not only for gathering information about the organization, but for involving all members of the system in the change process (Curtis & Metz, 1986).

Once the needs of the system have been clearly identified, the resources available that may be relevant to addressing those needs are examined through input evaluation. The skills and resources of the staff, support of parents and district personnel, and financial resources are examples of factors to be considered. When focusing on problems, it is sometimes easy to overlook the importance of acknowledging and building upon the existing strengths, resources, and successes of the system. Attitudinal factors may be just as important as tangible resources. The planning stage of system-level consultation is directly parallel to the intent of the problem analysis stage of the problem-solving process used in individual consultation. A thorough understanding of all relevant factors, both negative and positive, must be developed before moving forward.

COMMITMENT OF KEY PERSONNEL

Because successful change requires a large investment of staff time and effort, voluntary participation is desired. In addition, the high level of involvement necessitates the commitment of key personnel. At the very least, such persons cannot be obstacles if the change effort is to succeed.

Gatekeepers. It is essential to identify all "gatekeepers" before any aspect of the change process is initiated, including diagnostic evaluation. The role of the gatekeeper is characterized by decision-making power, ability to distribute resources, and authority within the system. They must not only give sanction for the change process, but it is hoped provide support and fully participate with all other members of the system. Sometimes, just the nonparticipation of the gatekeeper can be a negative factor to be considered. The role of gatekeeper is most commonly held by personnel such as the principal or superintendent. However, staff in less obviously powerful positions, such as the school secretary or specific teachers, can be very influential in determining the success or failure of change efforts.

If a person in a gatekeeping position is identified as being an obstacle to desired change, the school psychologist can use a structured problem-solving process, such as that described below, to reduce or eliminate the negative influence of the individual. Any identified obstacle to change or organizational problem should be addressed in a planned and systematic manner, using a structured problem-solving process. The discussion below includes an illustration of using such a process in this way.

Involvement of all Stakeholders. In addition to securing the commitment of gatekeepers, all stakeholders in the system must participate in every stage of the change process. This is a fundamental principle for organizational change. Stakeholders are all members of the system who will be affected by the change. Decisions about system-level change in schools are often made at the administrative level. Failure to involve important stakeholders, such as classroom teachers, will negatively impact the organizational change effort.

Many efforts to implement intervention assistance programs in schools have violated this fundamental rule. Typically, the discussions, planning, and even implementation of changes have involved seemingly everyone, *but* classroom teachers. Principals, special education personnel, school psychologists, and other related services professionals then "inform" teachers about the new procedures. Confusion and frustration result among these well-intentioned change agents when teachers are not included early in the process. Common sense suggests that classroom teachers are *the* primary stakeholders among the professional staff in a school who will be affected by the implementation changes, such as intervention assistance programs.

Parents represent another critical group of stakeholders. Parents are often glaringly absent from system-level change efforts in schools. The Individuals with Disabilities Education Act Amendments of 1997 mandate and describe how parents are to be meaningfully involved in the education of children with disabilities. However, the involvement of parents in all school change initiatives would seem self-evident from the perspective of the organizational change literature. It also should be apparent that, where possible and appropriate, students should be involved in systems change. The literature is very clear: *All* stakeholders should be meaningfully involved in every aspect of system-level change efforts, beginning with initial discussions regarding *potential* change and continuing through implementation.

Demonstrating Change Strategies. Because an organizational change effort must be planned and sustained over time, it is important that key personnel and other stakeholders have a realistic understanding

238

of what may be involved. Otherwise, the absence of immediate change (an unrealistic goal to begin with) could lead to the loss of commitment and investment in the process. Therefore, it may be helpful to demonstrate change methods so the group can gain familiarity with such procedures, as well as experience success in addressing real concerns. Curtis and Metz (1986) taught an entire school staff group problem-solving techniques as a means for demonstrating organizational change methods and for securing their commitment to the change process. After having the participants identify real concerns and establish related goals for change, group problem-solving skills were taught and used to develop strategies to address the concerns and achieve the identified goals. Using this strategy served to teach the problem-solving skills necessary for planned change, while addressing real concerns that were considered important by the participants.

Goal Identification

Based on diagnostic and input evaluations, specific desirable outcomes should be identified. It is critical that these goals reflect information derived during the problem analysis procedures. The goals will determine the types of system-level intervention to be considered, and specifically those chosen for implementation. It is at this stage that groups often discover that they have identified several different, although related goals. Refinement of goals and the selection of one goal at a time to pursue through specific change strategies will enhance the likelihood that the group will be successful in its efforts.

It is also important to establish *realistic, concrete, system-level goals*, especially during the early stages of an organizational change effort. When seeking organizational change, it is easy to get lost in an "all-or-nothing" view of the system. The school psychologist can assist the group in breaking larger goals into more reasonable steps according to which change can be measured. Even a small initial change has the potential to create a ripple effect that leads to more significant change later. For example, one school psychologist began by regularly scheduling only 15 minutes each week to talk with the building principal about building-level issues. After a few weeks of such talks, an interesting journal article related to one of the issues discussed would occasionally be given to the principal. Over time, the school psychologist came to be viewed by the principal as a source of information and expertise regarding a broader range of issues, particularly as they pertained to organizational concerns.

Strategy Development and Implementation

System-level consultation involves ongoing activities to address long-term goals. Intervention is not conceptualized as a single event. Therefore, it is helpful to identify a staff member who will serve as the on-site facilitator of the change process. Although school psychologists may be well suited for this role, the itinerant nature of some school psychology assignments may make involvement in the on-going monitoring of change difficult. In system change efforts, it is easy for individuals to get lost in the details of their daily routines. It is essential that someone monitor system-level initiatives and, when necessary, refocus the group on the change process.

The overall plan for change may involve intervention methods that target the cognitive, affective, and/or structural components of the organization. Interventions that address cognitive aspects would include the activities that are instructional such as training staff in new technology or practice. Affective interventions are those that address interpersonal relationships among the staff. Examples include training in communication and effective listening skills. Structural interventions focus on the way the organization is put together and its relationship to the various subsystems and suprasystems. Because these components are somewhat interrelated, system-level intervention plans that address all three are usually most effective. The intervention activities should be carefully selected to achieve aspects of the overall goals of the system.

TEACHING PLANNING AND PROBLEM-SOLVING PROCEDURES

As noted above, the development of problem-solving skills by the system is the primary goal of system-level consultation. The most effective method for achieving this goal is through direct instruction, practice, and follow-up. The school psychologist could be a valuable resource in providing training to as many of the major stakeholders in the system as possible. The effectiveness of the system will increase as the proportion of its members who are effective problem solvers increases.

It may be necessary to begin by training only a few members; however, providing all members with training in problem-solving skills should still be maintained as an eventual goal. For example, in working at the building level, it very often is necessary to begin by training a specific group such as the local school improvement team. Once the group has been trained, had an opportunity to practice using collaborative planning and problem solving procedures, and then refined their use of such methods through feedback, discussion, and perhaps further training, they can become a vehicle for planning training for the remainder of the staff. However, improving the problem-solving skills of any members of the system represents progress, even if training the entire staff is not possible. Any improvement should be recognized as a positive outcome of system change efforts.

Although many different approaches to problem solving might be used, the model described below has been used by the authors to train a wide range of individuals and groups in a variety of settings, including schools, agencies, and professional organizations. Each of the steps is explained briefly. Then an example is provided which is based on the actual work of a school-based intervention assistance team.

A MODEL FOR COLLABORATIVE PLANNING AND PROBLEM SOLVING

The effectiveness of this model is dependent on conscientious adherence to following the steps described in sequential order, thoroughly completing one step before moving on to the next. For ease of presentation, each step is explained in terms of *problem-solving* procedures. However, the same steps may be used to achieve goals identified for the purpose of *planning*.

1. *Describe the problem or concern as concretely and as specifically as possible. Once the problem has been defined, identify the desired outcome of the problem-solving efforts, again using concrete, descriptive terms*: Often, what initially is thought to be a problem, once analyzed, is recognized to be several distinct, although perhaps related problems. Record all problems identified. Although all of them may not be dealt with during a particular session, once recorded, they can be addressed during subsequent sessions. Identify the specific problem that will be addressed *first*. Then, define the desired outcome that would result from resolution of only that specific problem. It is essential that all members of the problem-solving team have the same understanding of the problem to be addressed and of the desired outcome.

2. *Analyze the specific problem chosen in terms of factors that might help in addressing it (resources) and factors that serve as obstacles to its resolution:* Using a brainstorming process, all members of the group participate in generating a list of resources and obstacles. The use of only concise statements should be encouraged. It is essential that ideas are not discussed, evaluated, or even clarified at this point. The intent is to produce as much information as possible by involving all members of the group in a free flow of ideas. Record only enough about each idea to allow clarification by its originator after brainstorming is completed. This should be recognized as an "idea" stage. At this point, there would have been no decisions made regarding actions to be carried out.

3. *Select one obstacle that is significant in terms of its hindrance to resolving the specific problem identified in Step 1:* The obstacle selected should be viewed as only the first obstacle to be addressed, not as the only one. It is best to avoid trying to identify the most important obstacle to reduce concerns relating to ownership associated with who generated specific ideas. However, the obstacle chosen should be one for which there is shared interest across the group. If the group were inexperienced in using structured problem-solving procedures, it also would be desirable to select an obstacle for which the group has a reasonable chance of generating possible solutions. Experiencing success is important in developing group skills and confidence. Other important obstacles can be noted for future attention.

4. *Focusing only on the one obstacle selected in Step 3, brainstorm resources and activities that might be used to reduce or eliminate that specific obstacle:* The list of resources identified in Step 2 serves only as a stimulus for the generation of ideas.

240

Again, because a brainstorming process is being used, the intent is to generate and record as many ideas as possible. Specific ideas can be clarified after brainstorming is complete. Remind participants that this is only an *idea* stage and that *no decisions have been made* regarding actual action plans.

5. *Design a concrete plan of action that reflects accountability for completion (i.e., who, what, when):* If possible, several action plans should be developed to address the same obstacle. In that way, if one plan is not carried out, or does not attain the desired results, the identified obstacle still may be reduced or eliminated through other actions. Each plan should clearly identify *who* (by name or position) is responsible for carrying out *what* specific activity (include as much detail as possible) by *what* date. Avoid stating any aspect of a plan in general terms; the greater the detail provided in a plan, the greater the likelihood that it will be carried out as intended and on time. Sometimes, it is desirable to try out an action plan on a limited scale before proceeding with full implementation. If the person identified as being responsible for the action plan is not a member of the group developing the plan, it is necessary to create an action plan that identifies a member of the group *who* will contact that individual about willingness to take responsibility for the action plan (what), and the date by which contact is to be made (when).

6. *Establish a procedure for follow-up and review:* Consider interim reporting dates and procedures to check on the progress of an action plan, rather than waiting until the deadline for its conclusion. This stage also is used to evaluate the effectiveness of action plans and for modifying them or even recycling to an earlier stage in the process.

Example of the Six-Step Problem-Solving Model. In order to clarify the problem-solving process within the limits of the space available, the following example includes only selected entries for some steps.

Original Concern: The teachers are not using the Intervention Assistance Team (IAT) as a means for helping them respond to the special needs of their students. Our goal is to increase from 10 to 40% of the teachers using the IAT by the end of the school year.

- *Step 1. Statement of Problem/Concern:* Many of the staff are unaware of the benefits they can receive from working with the Intervention Assistance Team.

- *Step 2. Analyze problem, identifying resources and obstacles to resolution.*

Resources	Obstacles
A. Some staff has used the process and realized benefits.	A. Intervention assistance is viewed as a barrier to testing.
B. Resource people have worked with other schools where process is working well.	B. We have not communicated very effectively with our staff about process and results. We haven't communicated very effectively with our staff about the intervention assistance process and the results.

- *Step 3. Select one obstacle.*

- *Step 4. Brainstorm ideas to reduce or eliminate selected obstacle:*
  A. Conduct an in-service on the benefits.
  B. Report regularly during staff meetings.
  C. Disseminate written reports on process and results.

- *Step 5. Design concrete plans of action (who, what, when):*
  - **Action Plan 1:** Sue, Anne, and Mr. Allen will make a presentation at the staff meeting on March 10 about the process and how it is intended to be a resource for teachers.
  - **Action Plan 2:** Jim will contact several of the teachers who have used the process and ask if they will report during the staff meeting on March 10 on the benefits they experienced. He will contact them by March 3.

- **Action Plan 3:** Mr. Allen will contact Jan Smith to ask if she will make a brief presentation during our staff meeting on March 10 regarding the benefits being realized in some other buildings. He will contact her by March 3.

- *Step 6. Establish procedures for follow-up and review:* The Intervention Assistance Team will meet March 3 at 3:00 PM to review the plans for the inservice program and to make any final arrangements.

Evaluation

As with individual consultation or a student-focused intervention effort, frequent evaluation is essential for determining progress and for identifying the need for adjustments to the plan. It is essential that progress in system-level change efforts is also monitored and evaluated on an ongoing basis. Measuring progress is necessary at multiple levels, beginning with the lowest levels of the structured problem-solving process and progressing through the major goals of the organization.

1. How successfully was a specific action plan implemented and how effective was it in achieving the desired results (Step 5 in the Problem-Solving Process(e.g., presentations to the staff by several teachers who have been helped by the Intervention Assistance Team))?

2. How effective was a group of related action plans in reducing or eliminating the targeted obstacle (Step 3 (e.g., We have not communicated very effectively with our staff about the intervention assistance process and the results))?

3. As more obstacles are targeted and action plans developed and implemented, to what extent has the identified problem been reduced or resolved or the identified goal been achieved (Step 1 (e.g., Many of the staff are unaware of the benefits they can receive from working with the Intervention Assistance Team))?

4. To what extent has a system-level goal been achieved (e.g., Our goal is to increase from 10% to 40% of the teachers using the IAT by the end of the school year.)

Evaluation at each level enables you to determine the extent to which the problem-solving strategy has been successful. When necessary, the strategy can be modified or replaced by a new action plan. When successful, a new obstacle can be targeted or a new problem or goal identified.

SUMMARY

Major forces affecting education in general, services for students with disabilities, and school psychological services have created a tremendous need for professionals with knowledge and skills in system-level consultation and organizational change. Many opportunities exist for school psychologists to respond to that need by expanding their roles to include this area of professional expertise. By building on current competencies, school psychologists can increase participation in system-level change efforts by viewing behavior from a systems perspective, using collaborative planning and problem solving procedures, and pursuing strategies that are based in principles for organizational change. Any planned change effort, no matter how small, can be an important step toward improved services for students.

ANNOTATED BIBLIOGRAPHY

Fullan, M. (1995). *Change forces: The sequel.* Levittown, PA: Falmer.

Following on this well-known author's earlier work, *Change Forces*, this publication examines the pitfalls and opportunities of school-based change strategies. The numerous illustrations, based on actual change efforts in which the author has been involved, make this a particularly helpful work for school-based teams.

Senge, P. (1990). *The fifth discipline.* New York: Doubleday.

In this publication, the author introduces and advances the concept of the "learning organization," (i.e., the organization that is continuously engaged in developing the capacity both to respond to current opportunities and problems and to anticipate and prepare for the future). While well known organizational principles still serve as the cornerstone for much of this work, an intriguing and stimulating new way to think about organizations systems is offered.

Senge, P. (1999). *The dance of change: Challenges to sustaining momentum in learning organizations.* New York: Currency/Doubleday.

Much like *The Fifth Discipline Fieldbook*, Senge has written a helpful "how-to" book describing activities and strategies to use in addressing specific types of problems relating to change efforts. The discussion is organized according to three major areas: The Challenge of Initiating Change, The Challenge of Sustaining Transformation, and The Challenge of Redesigning and Rethinking, with activities relating to specific types of problems included under each (e.g., Not Enough Time Under Initiating Change).

Senge, P. M., Kleiner, A., Roberts, C., Ross, R. B., & Smith, B. J. (1994). *The fifth discipline fieldbook.* New York: Doubleday.
This publication was intended as a follow-up piece to *The Fifth Discipline* to, according to the authors, answer the question, "What do I do on Monday morning?" Numerous pragmatic strategies for systems change are discussed, using a wide range of differing organizations as illustrations.

Best Practices in Facilitating School Reform, Organizational Change, and Strategic Planning

Howard M. Knoff
University of South Florida

OVERVIEW

Over at least the past decade, virtually every state and school district in the country has worked in the area of comprehensive school reform in order to improve the academic and social-behavioral outcomes of all students. Guided by our eight national education goals (National Education Goals Panel, 1999), these schools have attempted to integrate all of their systems—organization, instruction, professional development, and management—into a common, articulated, and accountable process leading to substantive and meaningful results. In doing this, four fundamental questions continue to be asked:

1. How do schools design and deliver *an academic program* that successfully addresses the needs of all students while improving their rate of learning such that they progress through the grade levels and graduate from high school with functional and extended skills; and how do we create a functional assessment and evaluation system that is curriculum-based and that is used to design effective instruction and develop strategic interventions (when needed) that have a high probability of success?

2. How do schools design and deliver *a social-behavioral program* that increases all students' interpersonal, problem-solving, and conflict resolution (i.e., social) skills; how do we increase students' academic engagement and their academic task persistence and confidence; and how do we create a functional assessment and evaluation system that is setting-based and that is used to develop and evaluate interventions (when needed) that have a high probability of success?

3. How do we increase *the involvement of parents* in supporting and reinforcing the education of all students; how do we design and deliver an integrated or unified educational system that does not differentiate regular education and special education; and how do we facilitate *real* interagency and community cooperation, integration, and streamlining of services?

4. Finally, how do we accomplish all of this through a strategic planning process that incorporates *a data management system* that guides decision making and provides routine formative and summative evaluations, and how do we institutionalize this process such that it becomes self-generating, self-replicating, and responsive to current and future student needs?

All of these needs and questions are of great national importance. This is clear given a number of reports issued over the past few years and the current status of our nation's school reform movement. Relative to the latter, our country's schools and students have not made great progress on many of the National Education Goals (National Education Goals Panel, 1999), our current educational system still largely dichotomizes regular and special education, and our special education numbers continue to climb (U.S.

Department of Education., 1999), and many special education students still are not included in our state and national academic assessment programs (National Center on Educational Outcomes, 1997).

Relative to the former, the impact of race and poverty, especially on disabled and at-risk students, cannot be ignored. Indeed, the National Council on Disability's (1993) report, *Meeting the Unique Needs of Minorities with Disabilities*, is still relevant today in its statement that, "The present education system is overloaded and confused. Poverty, racism, cultural differences, the dissolution of families, and the weakening of home influences are among the contributing social factors that challenge the schools. When these variables are combined with low self-esteem, peer pressure, lack of self-discipline, and inadequate role models, students do not arrive at school ready to learn. To exacerbate the situation, those who are prepared to learn are often subjected to inappropriate curricula, inadequate support services, and, in some instances, a hostile school environment" (pg. 19). A separate report, *Mapping Out the National Assessment of Title 1: The Interim Report* (U.S. Department of Education, 1996), indicated that students in high-poverty schools lost ground academically relative to students in other schools between assessments in 1984 and 1992. Indeed, according to the report, state data show that by fourth grade there was already a large gap in reading proficiency between students in high-poverty schools and those in low poverty schools. These students were considered at-risk for academic difficulties, for possible special education services, and potentially for school dropout.

In the final analysis, it is apparent that schools still need an effective school reform blueprint that is driven by organizational change and strategic planning processes along with empirically demonstrated procedures and interventions. Related to this, they also need an effective training and leadership development process in order for real change (and prevention) to occur for all of our students. Finally, they need systematic ways of collecting data to analyze and determine the efficacy of their implementation processes. Critically, this blueprint must also be responsive to changes in the reauthorization of IDEA, including the mandate for parent involvement, to the need for more functional assessment in the classroom leading to more efficacious services (rather than labels), and to a goal of serving more special education students in the regular settings (Fuchs & Fuchs, 1992; Reschly & Ysseldyke, 1995). Finally, this blueprint must be based on proven, replicable models that involve exemplary practice and demonstrated outcomes.

Relative to low-performing schools, this blueprint also should be responsive to some "lessons already learned." One set of lessons was publicized by the Annie E. Casey Foundation (1995) based on a 5-year, five community New Futures grant program to prepare disadvantaged urban youth for successful lives as adults. After investing an average of $10 million in each community over 5 years, the foundation evaluated the implementation and planned change process such that future programs could be more efficient on the road to effectiveness. In the end, the key lesson was that, in the low-income communities involved, service-system and institutional-change initiatives, by themselves, could not transform poor educational, school, and health outcomes for vulnerable children and families. That is, institutional change was not enough; the comprehensive change process required home school and community collaboration that included social-capital and other economic-development initiatives that targeted entire low-income neighborhoods. Among the other lessons described in this report were:

1. Comprehensive reforms are very difficult and involve, at times, the path of most resistance. True integration at the service-delivery level requires collective decision making across budgeting, staffing, and resource allocation; good communication and clear program planning, purpose, design, and expectations; attention to issues of power, race, and ethnicity; and time, trust, risk-taking, and perseverance.

2. Comprehensive reform requires advanced and ongoing efforts to build constituencies that are committed to long-term efforts, to strategic planning, and to the development of systems that can sustain the change process over time and through changes in leadership.
3. Comprehensive reform is not for every community, nor is every community at a readiness level to begin this process. Comprehensive reform efforts must be planned, public, realistic, and shared; and they need core leadership, management systems and

skills, conviction and momentum, and credibility and legitimacy to have any hope of success.

4. Comprehensive reform requires a blend of outside technical assistance and local commitment, leadership, planning, funding, and evaluation that results in local ownership and self-renewal.

5. Comprehensive reform requires repair, revision, reassessment, and recommitment. Significant modification should not be interpreted as a sign of failure.

6. Comprehensive reform often requires the development of entirely new systems and ways of being. The alteration of existing systems or the implementation of new systems built alongside old systems often will not lead to real change and enduring outcomes.

Organizational Change: Initial Perspectives

In the context of school reform (or any other planned change process), it is important to note that organizational change and strategic planning should be natural, necessary, and ongoing components of a healthy, evolving school. Moreover, while schools need to focus predominantly on student outcomes, organizational change and strategic planning processes help them to recognize that some seemingly child-specific problems are actually building, systems, or community problems that must be addressed at multiple levels using a problem-solving process resulting in systematic, multifaceted intervention, and substantive change. Finally, while organizational change and strategic planning processes are generally guided by a representative group of school staff (including, often, parents and community leaders) who work under the guidance of one or two facilitators, these facilitators are chosen more for their leadership skills than because they come from a specific professional area.

It is also important to note that, until recently, individual schools have rarely engaged in systematic organizational development and strategic planning processes (see the Annotated Bibliography for examples of schools who have; also Knoff & Batsche, 1995). And yet, while many states have mandated annual "School Improvement Plans" generated by school-based strategic planning teams, few schools have been systematically trained and supervised in these processes, nor have they developed the team and consensus-building capacities needed for success. Commenting on these and other school reform initiatives, Sarason (1990) predicted their continued failure because:

1. School leaders do not understand that schools exist coequally to facilitate the development and growth of both students and educational personnel.

2. School personnel do not want to confront and change the existing power relationships among administration, teachers, other staff, and parents such that true collaboration and shared decision making can exist.

3. Those "facilitating" the reform process do not understand their schools and/or the reform process in the context of their histories or larger social systems. Rather than just looking for the causes and solutions of "system problems," they should also be generating the resources needed to reconceptualize and redesign new systems.

4. School leaders do not understand that, left unchecked, schools will respond to reform in ways that minimize the effort needed and the degree of real change required. This avoidance response, however, is directly correlated with the degree of powerlessness felt by those most responsible for the change.

5. Finally, many schools and communities still do not understand how issues of racial, cultural, and socio-economic status and composition influence the schooling process. Others do not know how to initiate and maintain discussions of these issues such that diversity becomes a characteristic of strength that results in a community working together to raise and educate all of its children.

In the end, successful school reform requires training and experience in the change process. And without this and a guided organizational change and strategic planning process that involves parents, community leaders, *and* school personnel, district- or building-based change will be extremely difficult to accomplish. The first step in this process is that all of these parties need to learn *how* to collaborate and strategically plan for school-based reform. Critically, this learning may take from 3 to 5 years, it may require an outside consultant or a full-time staff facilitator, and it may be especially challenging because the school will be implementing the change process at the same time that its management or advisory team is learning it. But, it must be done, it must be focused on increasing students' social and academic learning and development, and school psychologists must be involved—potentially as the primary facilitators of the process. By way of summary, Louis (1986) has argued that

> under the right circumstances, change orchestrated at the school level has a significant chance of making a difference. . . . Our best bet for improving school lies not with fine-tuning state reforms (although some of these are, of course, necessary) but with stimulating individual schools to change and providing them with appropriate assistance. A number of studies suggest that both process assistance (help in guiding the school's progress through change programs) and specialized training (to provide staff with new skills) are needed to implement significant change (p.34).

BASIC CONSIDERATIONS

To coordinate and facilitate a school-based organizational change and strategic planning process, school psychologists must understand and have expertise in three primary areas: (a) the problem-solving and planning cycles of a school from an organizational perspective, (b) the characteristics of an operating school district from a systemic perspective, and (c) the steps in a strategic planning process. Each of these will be discussed in detail below.

Planning and Problem-Solving From a District Perspective

Problem solving is needed and occurs in virtually every area of our personal and professional lives. Similarly, problem solving is used in virtually every area of business, politics, education, human services, and civic planning. Although some use more or fewer stages, problem solving, typically, is separated into four sequential stages: problem identification, problem analysis, intervention, and evaluation. Using an organizational context:

1. The *problem identification stage* involves actions that help (a) to operationally define the referred problem, whether of an individual nature or an organizational nature; (b) to specify the goals of the consultation, problem solving, and/or planning process; and (c) to begin to verify the existence and extent of the problem and to generate hypotheses to explain why the problem is occurring.

2. The *problem analysis stage* involves actions whereby (a) the referred and operationalized problem is fully investigated in all of its ecological, organizational, situational, and behavioral contexts; (b) the hypotheses generated to explain the problem are assessed and confirmed or rejected; and (c) interventions related to the confirmed hypotheses are identified and developed while their potential acceptability, social validity, treatment integrity, and generalizability are concurrently evaluated.

3. The *intervention stage* involves actions that include (a) the development of the organization and its members' capacity to implement the intervention plan; (b) the identification of criteria to determine whether the intervention has been successful or not, the method(s) to evaluate this success, and an estimate of the amount of time needed to begin to see this success; (c) the actual implementation of the intervention plan; and (d) the determination as to whether revisions or adaptations of the intervention are necessary to increase its effectiveness or to respond to unexpected outcomes.

4. Finally, the *evaluation stage* determines (a) formatively and summatively, whether the goals of the problem-solving process and the intervention have been met; (b) how the intervention's implementation process was qualitatively perceived; (c) how long the intervention plan should be continued and if it needs to be changed, faded out, or discontinued as a function of continuing success; and (d) to what degree the organization and its members can

independently continue the intervention and whether ongoing consultation and problem solving is needed.

Significantly, individual schools attempting school reform must recognize that different parts of the school system use the same problem solving process, yet they use this process in different time cycles (see Figure 1). This not only makes school-based reform a more complex process, especially as the school district is larger and more bureaucratic, but it also reinforces the need for strategic planning. As an example, most schools do their budgeting and grade-level planning in 1 year, action-planning cycles. Often, this begins by January or February at the latest, and it is completed no later than March when the school must submit its budget to an assistant or area superintendent or a business manager. From a school reform perspective, it is important to recognize the symbiotic relationship between school improvement goals and the budgeting process. While the ideal situation would have the goals determining how much of the total budget to dedicate to instruction and student progress, reality dictates that a lower than desired percent of a school's budget goes to school reform and that schools must prioritize their goals within the limited dollars provided. Another reality that must be integrated into the school reform process is that individual schools typically budget themselves on an annual basis. While businesses can set 5-year goals and budget accordingly, the annual nature of each school's budget and *the lack of significant carry-over funds* makes long-term goal setting and attainment very difficult.

Figure 1. Problem solving within school districs as correlated with time and planning cycles

Monthly Cycle or Less

Within a school, most grade-level teams (e.g., in an elementary school) or departments (e.g., in a high school) can respond to specific problems within a month or two (so long as they do not involve major financial expenditures), and they can determine the success of their problem solving often within 3–5 months. Moreover, most *teachers* in a classroom can respond to a situation, through effective problem solving, in a matter of a week or two, and then see the impact of their efforts within a month's time. The point here is that the closer one gets to the classroom level, the faster the problem-solving or action-planning cycle can occur. At a building level, problems are typically more complex, they often have budget, scheduling, or personnel implications, and thus, the problem solving often requires many months and sometimes can only be addressed across school years.

At a *district*-level, problem solving and action planning typically occurs in 3- to 7-year cycles. Essentially, this means that school-based problems that require district-level change have to wait until the planning, budgeting, and implementation cycle phases in, and that some problems may be addressed by the district only if those problems occur across a significant number of schools. As an example, a school may find that the newly adopted reading series is not sensitive to the background and culture of its lower SES and at-risk students. Since most districts purchase their basic academic textbook series (e.g., in reading, math, spelling) in, at least, 5- to 7-year cycles, this problem is likely to persist until the next series is adopted, unless the school chooses to expend a great deal of time and money to review and buy a new series earlier. Even from a policy level, most school districts take from 2 to 4 years to implement any new policy into practice if it involves acceptance, dissemination, training, and execution.

To summarize this section on planning and problem solving, please refer to Figure 1, which diagrammatically shows the problem-solving process across the multiple time cycles that exist within a school district. From an organizational perspective, the strategic sequencing and integration of these cycles is critical, as is the district's capacity to streamline some of these cycles at times, while recognizing that not all change can occur immediately or simultaneously. Finally, the importance of the evaluation stage must be emphasized once again. If the desired outcomes of problem solving are not occurring, then all four stages must be reviewed. More specifically, the wrong problem may have been identified, it may have been analyzed incorrectly, the wrong interventions may have been chosen or they may have been implemented without treatment integrity, or the evaluation methods, themselves, may be providing false or negative readings when acceptable results actually have occurred.

Characteristics of an Operating School District

To facilitate organizational change and do strategic planning, school psychologists must understand the characteristics and interdependencies within an operating school district. With this and an understanding of the developmental and critical-events history of the school district, certain processes (such as specific power relationships, how decisions are made and by whom, how particular people were appointed to their current positions) become more comprehensible, and others that are critical to the change process become more predictable. In the end, however, organizational change is not always a systematic, cause-and-effect process. Clearly, it is always easier for a strong leader to facilitate change when entering a system in crisis, or near-crisis, or a system that is frustrated with chronic inertia and mismanagement. Similarly, a well-developed strategic plan can be thwarted by a crisis event (e.g., a community's rejection of a bond issue, the death of an important staff person, or a natural crisis such as a hurricane or a flood) that may completely derail the process for many years.

Below, the characteristics of an operating school district will be briefly described (see Figure 2). These have been adapted from Egan (1985), and they are organized in four major systems: the Receiving System, the Performance System, the Human Resources and People System, and the Pervasive System Variables. In total, the school system must be viewed as an ecological system that includes the home and the community, and it must be recognized that this ecological system both creates and identifies its own problems *and* has the resources and capacity for innovation to solve these problems.

RECEIVING SYSTEM

Refocusing our perspective back onto the school building, the receiving system is composed of our primary clients, the school children whom we serve, and

our primary goal is to create and maintain an operating system that maximizes their social, emotional, behavioral, and academic development and progress. Critically, however, the organizational change and strategic planning process may identify secondary goals and interventions that involve other clients, such as families and younger preschool students that preventively help to support our primary goals. In fact, given the pervasive impact of poverty, the still-high number of teenaged and single parents, the increasing number of students who are not socially and academically prepared when they enter school, and the number of young children from homes where both parents work—often within months of a child's birth—the inclusion of families and younger siblings in the school's Receiving System makes eminent sense.

In analyzing the Receiving System, the answers to a number of questions, beyond *Who are our primary or targeted clients?* become critical. These questions include: *What are our clients' needs? What do* they *identify as their own needs? What are their prescribed versus* felt *needs? What are their goals?* and *How attainable do they feel that these goals are?* From a strategic planning perspective, the answers to many of these questions will require both a client needs assessment and, at least, a demographic, social, and historical analysis of a cross-section of the homes and communities served by the school. From an advocacy perspective, we need to make sure that we are integrating and reflecting the *real* needs, goals, and desires of our clients into our organizational change process, and that we are not choosing only those goals that are convenient or expedient. Significantly, advocates often are not members of the groups they advocate for and, thus, sometimes they never fully understand these groups, their subtle needs, and reasons behind those needs. Comer (1994) reflects this when he said:

> A child develops a strong emotional bond to competent caretakers—usually parents—that enables them to help that child develop. . . in social, psychological, emotional, moral, linguistic, and cognitive areas [that] are critical for future academic learning. The attitudes, values, and behaviors of the family and its social network strongly affect such development. A child whose development meshes with the mainstream values encountered at school will be prepared to achieve at the level of his or her ability. In addition, the meshing of home and school fosters development: When a child's social skills are considered appropriate by the teacher, they elicit positive reactions. A bond develops between the child and teacher, who can now join in supporting the overall development of the child (p. 2).

The goals in all of this is are (a) to identify those client groups most related to the social and academic progress of the students in the school; (b) to analyze their strengths, weaknesses, resources, and limitations; (c) to understand home, community, and other historical and environmental characteristics that influence student progress; (d) to determine how client and environmental strengths and assets positively impact student progress; and especially (e) to assess *why* client and environmental weaknesses exist such that school reform goals can target resolution and growth. In doing this, primary, secondary, and tertiary prevention interventions likely will emerge. Ultimately, however, the organizational change process should focus on primary and secondary interventions at a system and building level, and on providing educational personnel the skills and resources to implement the tertiary prevention interventions at a building and classroom level.

PERFORMANCE SYSTEM

The Performance System involves the organizational and strategic planning aspects of a building's system that help it to reach its student-focused academic and social, emotional, and behavioral goals. Minimally, there are five elements to this system: the building's mission; the major aims or goals of the building that are consistent with and operationalized from the mission; the tasks, programs, or activities that will lead to the attainment of the aims; the materials and resources needed by the school's personnel to implement the programs or activities; and the specific outcomes that each program will accomplish that, again, should cumulatively lead to the realization of the building's overall goals and the accomplishment of its mission.

A building's mission statement should identify the purpose for the organization's existence, its targeted "consumers," its desired outcomes, and how, within a particular philosophical framework, those outcomes will be attained. This mission statement should be brief, specific, and clear, but given its importance to the strategic planning process, it should not sacrifice length for its ability to communicate and motivate. Indeed, the mission statement should be that statement that everyone in the organization points to as their defining purpose, and it should be the crystallizing perspective that integrates the Performance System with the Receiving System. As such, in the strategic planning process, the (re)development of the mission statement most often follows the organizational and needs assessment and situational and environmental analysis steps. Below are two mission statement examples, one from a school district and the other from a school building. Note that the building statement is somewhat more specific and tailored to its distinct population and circumstances.

1. The General County School District is dedicated to enabling students to develop their individual capabilities for a lifetime of learning and for responsible, productive participation in a diverse and changing world.

2. The Specific Elementary School will prepare each child to meet life's challenges by providing the best possible learning environment with the most effective methods and resources to insure that each child will develop academically, socially, and aesthetically.

Often underlying the mission statement are a number of visions, philosophies, or beliefs agreed upon by the school as essential to everyone's acceptance of the mission statement. One set of beliefs, adapted from the Council of Administrators of Special Education's (1992) report, *A Future Agenda for Special Education: Creating a Unified Education System*, is as follows:

1. Everyone is responsible for the education of all students.

2. A unified system of education integrating regular and special education must prevail.

3. Accountability for all students is guaranteed through a system of unified outcomes.

4. All educators are prepared to educate all students.

5. Funding must support a unified system.

6. Site-based management is key.

7. A unified system requires a unified, yet flexible, curriculum that is shared among and with educators and that has specified outcomes.

8. Staff development encourages problem-solving, shared resources, and continuous improvement.

9. All families feel welcome and are involved in the schooling of their child.

10. All students and staff have access to and training in appropriate technology.

Clearly, the development of the mission statement and the generation of the goals that operationalize the mission statement will come more easily to the staff that embraces many or all of these beliefs.

As noted above, once the mission statement is developed, the building then should identify the major aims, programs, needed resources, and specific outcomes that will ensure building success. Often it makes sense to develop 3- or 5-year plans, specifying the major aims and outcomes only, and then a series of 1-year plans that, if implemented, will sequentially lead to the 3- or 5-year outcomes. The generation of these plans will be discussed later in the strategic planning section of this chapter. For now, it is important to emphasize the importance of identifying *a priori* outcomes that are relevant, observable, and measurable such that formative evaluations can be applied periodically to determine whether the programs chosen are meeting their intermediate goals or if problem solving and special intervention for these programs, due to less than successful outcomes, are needed.

HUMAN RESOURCES AND PEOPLE SYSTEM

This System involves all of the human resources within a school that are needed to implement the programs and accomplish the work that the school has identified in its strategic plan. Significantly, however, "human resources" also includes the personnel and process management of the individuals and teams needed such that the "whole is greater than the sum of its parts." To this end, then, schools must evaluate and coordinate their staff people, their respective roles and responsibilities, their relationships both to each other and to the school's goals and programs, and the process variables (e.g., leadership, communication, decision-making approaches) that make it all work together. Much of this, moreover, should be driven by the specific programs identified within the Performance System such that the entire school operating system becomes more integrated and planful.

To expand briefly, the important components of the Human Resources and People System are as follows:

1. The necessary *people* in the system are identified by the client, program, and management needs of the building. Client needs typically involve both the educational and mental health needs of the students and related family needs. This may necessitate both a strong cadre of primary educators and an equally strong support network of support professionals—educational specialists in particular curricular areas and health and mental health specialists such as school psychologists, social workers, school counselors, and nurse practitioners. While program needs may involve both educational and mental health specialists, the point here is that the programs identified in the Performance System must be staffed by individuals who can best meet the specified outcomes. At times, this will require hiring staff with special backgrounds and/or credentials. At other times, this will necessitate the training of existing staff such that the program(s) have the highest probability of success. Finally, the management needs of the building are also critical to the overall success of the building. These include personnel management and supervision, office and data management, transportation and food management, and grounds and security management. Once again, personnel to address the building's management needs could overlap with those dedicated to client and program needs. The issue, ultimately, becomes how these individuals are organized and to what degree they are integrated and satisfied with the level of integration required.

2. As noted above, the specification of building, program, and activity *roles and responsibilities* is important to determine whether the knowledge and skills needed for success exist in the building. Two points are especially important here. First, relative to the academic and social progress of students, the professional *title* of the individual providing an intervention, service, or program is basically irrelevant. What is relevant is that the individual has the ability to provide the desired skills. More specifically, and as an example, if a building decides that an anger control group is needed for certain students, it matters little whether that is done by a counselor, a clinical social worker, a school psychologist, or a teacher with special training so long as an appropriately trained professional fulfills the need. The second point is that staff training should always have three outcomes: the mastery of knowledge, the translation of that knowledge into functional skill, and the attainment of a level of staff confidence such that both the knowledge and skill levels are maintained over time. Unfortunately, staff training often is limited to one-day inservices that provide some knowledge but very little skill development and/or transfer into appropriate settings. Successful staff training provides both the foundation knowledge necessary to understand the topic at-hand and the skill development *and supervision* in the settings where the knowledge will be applied. While this may involve a significant investment in staff time, it also will reinforce the importance of the inservice area, ensure that staff have the skills needed to independently use the information with, for example, their students, and develop a level of staff confidence such that they will be able to apply the skills to new situations and to train new staff over the years in the lessons learned. In the end, the specification of the functional roles and responsibilities that a school needs to accomplish its goals is critical to both the building's personnel planning and development and to staff confidence and morale. While the division of labor and tasks could result in establishing new job descriptions, the use of broad and flexible job descriptions is recommended over those that link particular professions to stereotyped and overly specific jobs and activities. Ultimately, the skills, commitment, and personal interactions of the staff will more powerfully determine the building's success than the technical adequacy of the job description.

3. The *relationships and process variables* part of the Human Resources System qualitatively involves the monitoring and reinforcement of (a) the processes that integrate the needs of the client groups, the goals of the Performance System, and the personnel who will provide services; (b) the processes that create positive school and working climates; and (c) the processes that ensure good group interactions, sound communication, strong leadership, and appropriate decision making. In essence, the school psychologist working here is functioning as a process consultant or a human relations specialist, but clearly, this is not out of any psychologist's area of expertise. To accomplish

any task, one must always attend both to process and to content and outcomes. While content and outcome often determine whether a building has the skills or capacity to complete a goal, the process typically determines whether the skills are ever applied and to what degree. The issue here is productivity: Does a staff have the motivation and coordination to accomplish more than would be predicted by their raw skills alone, or will they accomplish only the bare minimum without regard for the loss that that entails to the students?

PERVASIVE SYSTEM VARIABLES

The Pervasive System Variables are building, district, and community variables that impact the Performance and Human Resources and People Systems in both positive and potentially negative ways (Evans, 1996; Fuhrman & O'Day, 1996). In essence, these are the macro-level variables that can affect system morale, motivation, and satisfaction. At the same time, many buildings are able to insulate themselves from these variables, especially when they impact at a district level, and create their own building-level norms and approaches such that they can accomplish far more than the dysfunctional district within which they exist. In total, there are six Pervasive System variables. Briefly, they are

1. The *Incentive/Reward Factors* are those formal and informal factors that motivate teachers and other building and district staff people to accomplish their educational goals. The most formal of these factors are the contracts that staff people are working under, and the conditions under which those contracts were negotiated and accepted. Numerous studies and public polls over the years have found that salary is not the most important motivating factor keeping our teachers and other educators in the classroom and profession (usually salary ranks anywhere from fourth to seventh). However, when appropriate raises are not forthcoming, when union-administration tension around a contract exists, and when strikes or other work-stoppages occur, staff motivation can decrease and the collaborative relationship between teachers and administrators (including building principals) may suffer. Overall, this can significantly interfere with the organizational change and strategic planning process, and its residual effects may persist for many years after the original contractual conflict has ended. On an informal level, building staff are most motivated by their own collaboration and accomplishments, their feeling that they are making a difference in their students' lives, their belief that they have some autonomy in determining what and how they want to teach, the building-level recognition that they receive from their peers, and the incentives available to them—for example, opportunities to participate in advanced training, district-level leadership activities, and innovative classroom and other programs. Critically, many of these informal, yet powerful, incentives and rewards should be identified by and integrated into the strategic planning process. Two important incentives are knowledge and time. Many organizational change programs require professional development or inservice training, and they provide this training (often using substitute teachers and release days) during the school day with follow-up grade- and cross-grade-level team meetings during other school days. Collectively, this training provides teachers with additional knowledge and skills that make them more effective and efficient in the classroom and with an additional incentive or "reward" of time during the professional day to learn and master these skills. In addition, the use of "school time" for professional development communicates the importance and role of the training provided and the fact that the organization respects the staff's time and professional commitment.

2. *Quality of Life and Climate Factors* coexist, to a large degree, with the incentive and reward factors. Elements of this factor include those tangible and intangible needs that must be present in order to get the work of the building done (e.g., books, sufficient desks, supportive teacher-principal relationships, appropriate provisions for safety). All of these elements ultimately converge to create a positive (or negative) school climate that creates or supports the motivation and morale discussed for the incentive factors above. While there are many operational definitions of positive school climate and many school climate scales, a synthesis of the school climate areas most identified and used include (a) a safe and orderly environment, (b) a

clear school mission with appropriate levels of planning and action and a good use of resources, (c) instructional leadership and smooth administration of the school, (d) opportunities for students to learn and stay on-task and high expectation for student social and academic achievement, (e) positive home school relations and parent involvement, (f) student involvement and influence, (g) good teacher and/or staff morale, and (h) positive race relations.

3. *Environmental Factors* include those community-based factors that directly or indirectly affect the management and organizational atmosphere of the school. These community-based factors include (a) the demographic and social, economic, governmental, and political status and/or circumstances of the neighborhood or broader community around the school and (b) issues related to population age and growth, families and households, minorities and race/ethnicity/gender status, crime, health, attitudes and values, personal income and employment, economic growth, housing, transportation, government income and expenditures, government support of the community and education, political participation, and philanthropy. In the context of strategic planning, many of these factors are evaluated in the context of an environmental scan and/or analysis. When doing this, the strengths, weaknesses, opportunities, and threats within the community, from the school's perspective, need to be appraised. Ultimately, the positive and/or negative impact of the environment on the school must be determined and integrated into the strategic planning process. Clearly, the environment potentially affects the school's quality of life and available resources, as well as the needs of both the clients and the staff. As a special case in the environmental factor domain, mention must be made of special events and circumstances that concurrently affect a community and its schools. Unfortunately, the best examples of these events tend to be catastrophic, but clearly, less intense circumstances also can be significant. As examples, then, one must recognize the economic, personal, and emotional impact of events such as (a) the bombing in Oklahoma City and the tragedy of Columbine High (and others); (b) Hurricane Andrew, the San Francisco/Oakland earthquakes, and other natural disasters; and (c) the more prevalent but less publicized situations involving threat, violence, loss, and death that occur in our classrooms, on our school grounds, and within our communities. These "environmental" events affect the day-to-day and year-to-year lives of our students and schools as much as the more-evident demographic and economic factors within our communities. And yet, many of these events have more long-standing and subtle impact over time, and thus, strategic plans and interventions are needed for them to prevent their long-term effects and turn their presence into opportunities for learning and prevention.

4. *Political Factors* occur both within the school district or building and outside of the district or in the community. While the within-district factors are implicit in the incentive and climate factors above, the out-of-district facets are particularly pertinent here. These political factors involve ways that outside stakeholders in the system utilize their formal and informal power (in overt and covert ways) to influence the status and direction of the schools. At a macrosystem level, these political factors include local governmental (e.g., financial or morale) support, the impact of school boards and their elections, the selection or election of the superintendent, the participation of the business community indirectly or through, for example, business partnerships, the involvement of advocacy and special interest groups. At a building level, they additionally include the involvement of the Parent Teachers Association, influential parents and community leaders, and specific client groups to the degree that they are organized or command attention. It must be noted that while politics often is considered negative and intrusive, this does not have to be the case. In fact, through a strategic planning process, government, business, and other community leaders can be integrated into a comprehensive and integrated plan of action such that the political system can be directly used to support the broader goals of the school and school district. In the end, most communities are willing to commit time, funds, and energy to a process when clear goals are identified and important outcomes are (potentially) realized. This is the typical and expected outcome of the organiza-

tional change process, and this process often can rise above a political system bent more on power and influence than equity and excellence.

5. *Cultural Factors* within a school or school system involve the stated and unstated values, beliefs, assumptions, norms, policies, and rules that affect the productivity of the school or system and its quality of life. From a historical perspective and like any complex organization, a school goes through specific life stages that reflect its development, personnel, clients, and goals and objectives. With the introduction of a new principal, with the turnover of significant staff members, with shifts in demographics, with new mandates from state or district levels, the school adjusts, develops new norms and procedures, and redefines its "culture" or way of doing business. Without the understanding of a school's culture, organizational change is more difficult, random, and tenuous. *With* this understanding, the positive aspects of the culture can be utilized, and the weaker aspects either isolated, minimized, or changed.

6. The *Arational Factors* within a system involve those dysfunctional, skewed, and unchangeable characteristics that interfere with the system's progress if allowed. While these characteristics typically can be identified and understood, they cannot be changed—or, at least, their change will take a monumental effort. These characteristics include system resistance, inertia, self-interest, unpredictability, emotionality, rejection of data, hidden agendas, and many more. At the very least, arational factors must be identified so that people within the system can agree to ignore or circumvent them and not be frustrated by their presence. At the very most, arational factors might be so strong within a system that organizational change should not or is not attempted. Given this latter situation, one organizational option is to literally dismantle the system so that a new and improved system can replace it.

Strategic Planning Process

Strategic planning is a systematic process that increasingly is being used in education to help schools and school districts to anticipate and plan their future directions while considering both internal and community-based strengths, weaknesses, threats, and opportunities (Schlechty, 1997). Designed to promote and encourage teamwork, strategic planning involves a number of systematic activities that initially may take a year or more to get into place. Nonetheless, once implemented, strategic planning often takes considerably less time as it (a) develops and monitors the programs and activities designed to meet the system's mission and goals, (b) tracks their progress over time, (c) makes mid-course adjustments, and (d) attempts to anticipate other, future events that may affect the school or school district in its pursuit of educational excellence. Ultimately, strategic planning introduces a systems perspective to education that emphasizes planning, cost- and time-efficiency, and maximum resource utilization. In the long run, it can help a school or school district to identify and rededicate itself to its primary mission and goals, and ensure that these goals are met effectively and efficiently.

Cook (1990) and Valentine (1991) provide two overlapping perspectives as to how strategic planning should occur. Cook divides the strategic planning process into five phases: Phase I: Creating a Base for Planning and Change; Phase II: Developing the Strategic Plan; Phase III: Developing the Implementation Plan; Phase IV: Implementing and Monitoring the Plan; and Phase V: Renewing the Plan. During Phase I, the school or district engages in the following activities:

1. An External Environmental Scan and Analysis where (a) economic, demographic, social, political, and education trends are analyzed; (b) national, state, regional, and local patterns in the trend areas above are evaluated; (c) scenarios that predict future environmental events and their impact on the school are created; and (d) school-based responses to the most likely scenarios, within the resources and the school's capabilities, are generated.

2. An Internal Organizational Scan and Analysis where the strengths (or assets), weaknesses (or limitations), resources (or opportunities), and barriers within the school are identified, guided by the organizational map described above and depicted in Figure 2.

3. An Analysis of Stakeholder Perceptions and Expectations (as described earlier) whereby client needs and community (political) goals are identified.

4. A Community Education Process that ties the entire process together (a) by helping the community to understand the data collected, the trends and scenarios identified, and the need for strategic planning and change and (b) by involving the community and its stakeholders as equal partners in the remaining phases of this planning and change process.

In Phase II, the strategic plan is written by taking the results of the external and internal scans and sequentially developing a vision statement, a mission statement, strategic goals, and an outline of the implementation plan. This plan is then reviewed by members of the planning team, by critical client and stakeholder groups, and by others who might be either politically or functionally important to the implementation process. Ultimately, the feedback from this review process is synthesized and evaluated, and a revision of the strategic plan is "finalized." According to Cook (1990), the Phase II process should take approximately 3 months, and even then it is expected that adaptations to the plan will occur over time.

In Phase III, the Implementation Plan is formalized through the development of district-wide and building-level plans. It is at this point that the coordination of the planning and budgeting time cycles shown in Figure 1 becomes critical. Relatedly, the Implementation Plan actually involves three components: a 3- to 5-year "Strategic Operational Plan," an "Annual Operational Plan," and a series of "Individual Performance Plans" for each personnel unit involved in the implementation process (United Way of America, 1989). More specifically, the Strategic Operational Plan should contain a series of operational goals and goal statements, a prioritization of these goals, the organizational unit(s) or department(s) responsible for each goal, the 3- to 5-year time frame for the completion of each goal, and the 3- to 5-year costs of the activities needed to accomplish each goal. The Annual Operational Plan should identify, *for each operational goal or sub-goal*, the action steps needed to accomplish the goal, the key results expected, the individuals responsible for taking the action steps, the resources and budget needed, the timelines (including beginning and end dates) required, and the evaluative process to determine the goal's attainment. Finally, an Individual Performance Plan should involve (a) a performance planning section with areas of responsibility, operational goals, action steps to achieve the goals, and goals priorities specified; and (b) a performance review section to document actual achievements, levels of goal achievement, continuing responsibilities, and overall performance ratings.

In Phase IV, the strategic plan is implemented and monitored using the annual operational plans and the individual performance plans. As activities are completed and sub-goals are accomplished, it may be necessary to adapt some timelines, budgets, responsibilities, or even some operational goals. This should be expected, and critically this should be done in the same planful way in which the original strategic plan was developed.

Finally, in Phase V, the renewal of the strategic plan is addressed. At this point, the school typically has accomplished a great deal, and yet it must determine if its strategic direction is still valid. To do this, the school and planning team should re-evaluate the external and internal environmental conditions since the original writing of the strategic plan, re-visit the mission statement and strategic goals, re-focus the strategic plan as necessary, and renew the organization's commitment and energies toward the next level of accomplishment.

Valentine (1991) organizes her strategic planning process into five levels: Level 1: The Pre-Planning Stage of the Planning Process; Level 2: Re-Defining the Organization's Direction; Level 3: Developing the Strategic Mind-Set; Level 4: Implementing Goals, Objectives, and Strategies; and Level 5: Reassessing and Institutionalizing the Change Process (see Figure 3). While Valentine's strategic planning process appears more complex and comprehensive than Cook's (1990), hers is actually just a more descriptive expansion. Thus, it is instructive to review her process as shown in Figure 3 and compare it to Cook's approach above. In the end, every facet of Valentine's model has already been described. It does, however, provide a good summary to this section of the chapter.

BEST PRACTICES IN THE AREA

From a strategic planning perspective, much of the discussion above has identified the critical steps and best practices in facilitating school-based organizational development and change. From a school psychological perspective, what remains is a discussion of the steps that school psychologists need to take in order to actually implement the change process. This will be discussed in five phases: Phase I: Initiating the Strategy; Phase II: Preparing for Implementation; Phase III: Training for Program Implementation; Phase IV: Implementing the Planned Change Process; and Phase V: Evaluating the Planned Change Process.

In Phase I, the school psychologist makes an administrative entrance into the school with the expressed goal of facilitating the strategic planning and organizational change process. While this process often requires a series of meetings for relationship-building and the clarification of change goals and objectives, it can move more quickly when the administration has a sound grasp on the organization's strengths and weaknesses and the commitment to true change. In accomplishing the tasks of this phase, the school psychologist:

1. Meets with the principal and/or the administrative team.

2. Orients the administrative staff and other key personnel as to the conceptual underpinnings of strategic planning and organizational change, and describes its goals, strategies, and likely outcomes.

3. Obtains administrative approval to proceed with the process, and contractually agrees on the official goals, outcomes, and timelines needed.

4. Identifies the key administrative and other participants with the principal and the coordinate structure that will facilitate the planned change process.

5. Begins to learn as much about the organization as possible including its organizational structure and personnel, formal and informal rules and norms, policies and procedures, and organizational history and environment.

During this phase, the school psychologist must determine (a) whether the building is organizationally and motivationally ready for strategic planning, (b) whether the school psychologist has the skills and resources to facilitate this particular change process, and (c) whether the school psychologist wants to. In making these decisions and in managing the entry process embedded in Phase I, the school psychologist should:

1. Assess his or her own personal skills and the organization's history of change efforts before agreeing to lead the consultation process.

2. Specify, at least informally, the amount of time, effort, and money that may be needed to complete different parts of the planning and change.

3. Clarify potential goal differences (e.g., administrative versus staff-driven change, crisis versus prevention-motivated change, outcome versus process change) between himself or herself and the administration.

4. Establish a written or verbal contract with the administration, making sure that outcomes, timelines, and areas of responsibility are explicit.

5. Emphasize that change is sequential and time-oriented, and that the ultimate goals are system efficacy and the ability to anticipate and prevent future problems.

6. Recognize and communicate the complexity of the consultation relationship relative to both staff and administration, discussing especially issues of dependency, authority, confidentiality, and competence.

In Phase II, the school psychologist begins the preparations for implementing the planned change process by making a formal entry with the building staff. At this point, the same groundwork completed earlier with the administration is covered, and the process from the environmental analysis and organizational assessment through the development of action plans is begun. In accomplishing the tasks of this phase, the school psychologist:

1. Re-enters the building at the staff level.

2. Orients the staff to the concepts, goals, and strategies of the planned change process.

3. Obtains staff agreement as to their participation, desires, and expected outcomes.

4. Identifies formal and informal key stakeholders and organizational gatekeepers.

5. Does a preliminary study of the building's organizational climate and climate change potential and its current mode of operation and functioning.

6. Establishes a Strategic Planning Team, representing a cross-section of the staff, to facilitate the organizational change process.

7. Completes the environmental analysis, organizational assessment, and other facets of the strategic planning process.

By Phase III, the Annual Operational Plans should be complete, and the school psychologist has identified the training needed by the building in order for the strategic plan to succeed. For example, given the goal of improving the social and academic skills of students in an elementary school, the staff may identify the need for social skills training, a curriculum-based assessment process tied to curricular interventions, and a parent involvement program. At this point the training program must be delivered such that staff has the knowledge, skill, and confidence to implement the various facets of the plan. During this process, the school psychologist also should monitor the staff's commitment and reactions to the training and the building's changing group climate. Critically, the school psychologist *should not* proceed to the actual implementation of the planned change process until all of the staff are trained in the needed skills and components.

In Phase IV, the planned change process is fully implemented, and in Phase V the process is formatively and summatively evaluated, looking at both outcome variables (e.g., increases in student achievement, decreases in student retentions and suspensions) and process variables (e.g., satisfaction with the change process, improvements in school climate). During these phases, the school psychologist should attend and respond to potential staff and administrative resistance, while ensuring that building personnel develop skills *in the planned change process itself* such that they are able to independently manage and renew the process over time. In the end, three questions become critical: Are we accomplishing our goals? Are we doing our job? How are we doing the job?

SUMMARY

This chapter has focused on the important steps and procedures that relate to school reform and that facilitate school-based organizational change and strategic planning. After providing a context and the assumptions reinforcing the need for such change and planning, the stages of problem solving were described focusing on both the individual school and the school district. The importance of coordinating the change process with a district's various planning and budgeting cycles was emphasized, and then the characteristics of an operating school district were described by analyzing the Receiving System, the Performance System, the Human Resources and People System, and the Pervasive System Variables. Two perspectives of strategic planning then were introduced with five phases being typical: Phase I: Creating a Base for Planning and Change; Phase II: Developing the Strategic Plan; Phase III: Developing the Implementation Plan; Phase IV: Implementing and Monitoring the Plan; and Phase V: Renewing the Plan. The chapter concluded with a discussion of the steps that school psychologists need to consider as they implement organizational change and strategic planning at the building level.

Throughout this chapter, it has been assumed that school psychologists can *and should* be primary facilitators in the organizational change and strategic planning process. Today's children are coming to the schoolhouse door significantly at-risk for both educational and social failure. School psychologists are *the best trained* mental health and educational specialists in the schools today. We *must* take responsibility for guiding our schools through a successful reform process—building on the lessons learned and avoiding the potential pitfalls present. With our success, we will ensure that the next generation of school children is prepared to succeed themselves—not just at the schoolhouse door, but when they leave that door to return to their homes, to enter the workforce, and to lead their communities.

ANNOTATED BIBLIOGRAPHY

American Institutes for Research. (1999). *An educators' guide to school-wide reform.* Arlington, VA: Educational Research Service.

A useful guide that briefly reviews and evaluates 24 comprehensive or school-wide approaches to school reform. Providing snapshots of each approach's implementation process, first-year adoption costs, and effects on student achievement, this guide also lists papers, articles, and books about the approaches and their effectiveness. While the guide does not endorse or discredit any of the approaches—trying, instead, to describe and objectively evaluate—this resource provides a good overview of many of the school reform approaches used nationwide with directions on how to pursue more information.

Darling-Hammond, L. (1997). *The right to learn: A blueprint for creating schools that work.* San Francisco: Jossey-Bass.

An important work by an educator and researcher who began her work as a public school teacher and has been involved in the policy and practice of school reform for many years. Darling-Hammond's book describes ways to significantly improve not only individual schools but the overall system of education. Focusing especially on the needs and diversity of students, this book addresses such topics as how to structure "learner-centered" schools, to staff schools for teaching and learning, to reinforce teaching as a profession, and to respond to standards without losing the educational process.

Sarason, S. B. (1990). *The predictable failure of educational reform: Can we change before it's too late?* San Francisco: Jossey-Bass.

Sarason, in his inimitable style, analyzes the American school system and its culture to determine whether the school reform process has any hope of success. Written through Sarason's experiences and interactions in the schools and with his typical incisive and no-holds-barred style, Sarason identifies the many pitfalls *at the school level* that, if left unattended to, predict the failure of the current reform process. Among these are the fact that educators do not understand the reform process, they are not willing to change the entire system, they do not want to deal with the issue of power between teachers and administrators, and they do not recognize that, unless pushed, individuals will do the least amount of reforming to get by.

Valentine, E. P. (1991). *Strategic management in education: A focus on strategic planning.* Boston: Allyn & Bacon.

This "book" (which is actually sold in a three-ring binder) provides a comprehensive strategic management model that is designed to assist the reader in guiding a school district through the strategic planning process. Supported by case studies and citations from the management literature, the book has three parts: Strategic Management—Its Role in Education; Planning for Strategic Change; and Creating Strategic Change Within the Organization. In addition, the book has over 30 step-by-step worksheets that operationalize the process and make the author's approach an easy one for anyone who understands the interdependent components of the school system to implement. This is a useful book that can help a reader to more completely understand the inner workings of strategic planning.

United Way of America. (1989). *Strategic management and United Way.* Alexandria, VA: Author.

If you ever wondered why the United Way is so successful, this will answer your question. In this systematic eight booklet set, the United Way describes in detail how to apply strategic management to community-wide planning and non-profit administration. These booklets divide strategic planning into a six-step process that includes environmental analysis, organizational assessment, strategic direction setting, the formation of strategic plans, implementation, and performance evaluation. Supplemented by the Introductory and the final "Putting It All Together' booklets, the reader has a comprehensive and practical resource that provides important insight and sequential procedures to the design and implementation of organizational analysis, strategic positioning, and change.

Best Practices in Standards-Based District-Wide Assessment

Mike L. Vanderwood
University of California-Riverside
Kristin M. Powers
California State-Long Beach

OVERVIEW

The educational standards movement is clearly one of the most important school reform activities of the last decade. Some authors (O'Neil, 1995; Shepard, 1993) suggest that standards are a response to *A Nation at Risk* (National Commission on Excellence in Education, 1983), which urged the identification of educational goals for all students. One of the first national efforts in the standards arena was the establishment of Mathematics standards in 1989 by the National Council of Teachers of Mathematics (NCTM). The success of the NCTM standards encouraged the development of standards in other areas including science, civics, dance, language arts, music, and social studies (Marzano and Kendall, 1996). In addition to the work of national organizations, 49 states have developed academic standards and the federal government has encouraged the use of standards through the Improving America's School Act (IASA) and other federal legislation.

Owing to the 1994 IASA legislation, the 49 states that have developed state standards are developing standards-based assessment systems that will in many cases replace traditional norm-referenced systems. According to the legislation, states must report progress on their approved standards by performance on assessment systems that are aligned to the standards. In essence, the federal legislation has caused a major shift in the type of assessments states are using that has in turn affected the type of assessments districts are using to supplement state testing (Hansche, 1998).

Significant debate has centered around the need for national standards and whether the standards movement will ever significantly impact education in the United States. Although Brandt (1995) suggests that national standards will not occur and a study by Gandal (1996) argues that most state standards are weak, the number of districts implementing standards-based reform has increased significantly in recent years (Marzano & Kendall, 1996). Standards-based reform not only addresses the content and skills that are taught but also how they are assessed and reported that requires significant change for those who develop and use assessment data.

As described in Figure 1, within the context of a problem-solving model, state and district assessment information can be used as sources of information for convergent data about student performance. The expectations for student performance are based on multiple sources of information that are distilled into district standards. The standards are used to guide instruction that focuses on higher-order thinking skills and is routinely informed by assessment information. Districts determine the progress of their students by using multiple sources of information that are based on a variety of assessment techniques. Teachers are encouraged to check on performance throughout the academic year with embedded assessment procedures. These informally administered tests are linked to the standards and intended to provide

teachers information about the student's performance in the standard area. Teachers are not required to wait until the end of the year to see if the students are meeting the district's or state's expectations. Although standards-based assessment systems are often primarily performance-based, best practice suggests using a multi-modal approach to assessment.

The intended advantage of standards-based district-wide assessment over traditional norm-referenced large-scale assessment is the more direct connection of the assessment to district expectations. Standards are the starting point for both instruction and assessment. Typically, standards-based assessments are criterion-referenced versus norm-referenced and the information from the assessment systems are generally reported differently than in traditional models. This chapter will review the basic characteristics of standards-based district-wide assessment systems with the purpose of providing school psychologists with information needed to gain an understanding of the quality of their district-wide assessment. Additionally, suggestions about how to include standards-based information into psychological reports will also be provided. Psychologists who want to develop an assessment system should turn to a more thorough source such as *A Comprehensive Guide To Designing Standards-Based Districts, Schools, and Classrooms* (Marzano & Kendall, 1996), which is reviewed in the Annotated Bibliography.

BASIC CONSIDERATIONS

Definition of Terms

In her seminal work (Ravitch, 1995), Diane Ravitch points out that the term "standard" is used in many fields and is usually connected to some form of evaluation. Although within the field of education there is not a universal definition of the term, most states create "content" and "performance" standards and use them to inform the development of standards-based assessments. Content standards describe what students should know and be able to do while performance standards specify how good is good enough. Benchmarks is another term used quite frequently, yet the definition is less clear. There are three different forms of benchmarks: (a) descriptions of information and skills students should be taught, (b) performance activities, and finally (c) performance tasks (which are very specific and contextualized performance activities). Marzano and Kendall (1996) suggest that states and districts should use the first definition of benchmarks in their documents, but also include sample performance activities and tasks.

Proficiency level is another term used quite often in standards-based assessment systems. Instead of focusing on a student's score or the average score for a classroom of students, terms such as "Advanced Proficient," "Proficient," or "Novice" are used instead to help teachers understand student performance. Typically, the cutoff scores used to separate the levels are created through a standard setting procedure that consists of obtaining consensus about the quality of the performance at each of the levels. In other words, a group of stakeholders, which could consist of content experts, teachers, parents, administrators, and students, decide on the performance criteria for each level and then determine cutoff scores. The criterion referenced approach is preferable to using set percentile ranks to separate levels (e.g., Proficient equals 40th to 70th percentile). One problem with the percentile approach is that same percentile scores on two different tests does not always equate to the same level of mastery of the content.

District administrators, principals, and teachers can use proficiency levels for goal setting and as a concise index of how much improvement has occurred. Teachers can set a goal to improve from having 20% of their students at the Proficient level or above, to having at least 70% at that level by the end of the year. Principals and district administrators can use the same approach at building or district levels and feel comfortable that by meeting the goals, students will be able to perform at an acceptable level.

Source of Standards and Alignment to Assessment

As previously mentioned, several national organizations created standards to help states guide their standards development and to attempt to influence the teaching of specific subjects. States and districts often start with these standards and other documents such as the *Content Knowledge: A Compendium of Standards and Benchmarks for K–12 Education* (Kendall & Marzano, 1997). A tenet of the standards movement is that each community (state or district) should ensure that the standards selected meet the needs of their population. States and districts often modify the standards to more appropriately represent the population they are serving.

One of the proposed strengths of a standards-based assessment system is the alignment between the standards and the assessment. As Webb (1997) points out, creating alignment between what is expected, what is taught, and what is assessed can significantly strengthen an education system. Some authors argue that because of the lack of alignment between standardized norm-referenced tests and instruction, these tests are unable to assess the impact of education reform or the progress of a particular student (Baker, Freeman, & Clayton, 1991). In fact, in a study of 25 states, most states did not have assessments aligned with their standards (Lagurada, Breckenridge, Hightower, & Adleman, 1994). Referring to Figure 1, in a standards-based system, alignment is created by starting with the standards and using them as a basis for instruction and assessment.

Purpose and Consequences of the Assessment

Standards-based district assessments may be used for each of the purposes of assessment identified by Salvia and Ysseldyke (1998): (a) accountability and program evaluation, (b) instructional planning and progress monitoring, (c) implementing and evaluating interventions, and (d) making entitlement decisions. In addition to providing useful information for all types of problem solving, standards-based districtwide assessments have the potential to bridge the gap between special and general education programs. The "disjointed incrementalism"(Reschly & Ysseldyke, 1995) that characterizes the poor coordination and curricular discontinuity between special and regular education programs is minimized when general and special education teachers, psychologists and other related service providers share common assessment tools, strategies and language.

A benefit of using standards-based assessments for making important educational decisions is a closer alignment between the assessment, curriculum, and district standards than afforded by commercial, norm referenced tests. In addition, standards-based assessments are commonly used for program evaluation. The close link between standards, curriculum, and assessment makes standards-based assessment a critical instructional tool. In the best cases, the assessments have been carefully selected or constructed to represent important learning objectives. They are designed to provide important information about student progress that can inform instruction. For example, an error analysis of a running record may indicate specific reading skills that need to be taught to a student or group of students who all make similar errors. Similarly, scoring student essays with the history rubric may identify specific skills such as "analyzing two or more cause and effect relationships" that are less well developed than other skills among the majority of students in a particular class.

Types of Assessment

Of course, the quality of the standards-based districtwide assessment can affect the utility of the information obtained. Because content and performance standards often target higher ordered (e.g., analyses, synthesis) and authentic skills, standards-based assessments are more often performance assessments than traditional multiple-choice tests. Performance assessments require students to construct rather than select a response, and therefore the skills the student applied in constructing a response may be judged and the type of mistakes the students make may become the target of future instruction. The benefits of the strong instructional relevance of performance assessments is sometimes off set by concerns about the psychometric limitations of performance assessments (Salvia & Ysseldyke, 1998). Inter-rater reliability is a concern because performance assessment results are based on teacher judgments. Intensive training on these assessment procedures, provided during the initial implementation and continuing thereafter in the form of booster-trainings, is essential to ensuring adequate inter-rater reliability. The inter-rater reliability of performance assessments, such as those listed above, can be greatly improved with adequate training, precisely defined rubrics, and anchor papers that describe the performance of students who meet various criteria (Linn, 1994; Salvia & Ysseldyke, 1998).

In addition to potential problems with inter-rater reliability, performance assessments are often criticized for their lack of generalizeability (Mehrens, 1992). Well-constructed performance experiences provide students with an opportunity to demonstrate the depth of their knowledge about a very specific subject (e.g., "photosynthesis"); however, it is not easy to generalize those results to how the student would perform on another task or subject (e.g., "evolution"). Unlike multiple-choice tests that can sample (some argue superficially) a wide range of student knowledge in a short period, performance assessments forfeit breadth of scope for greater depth of inquiry. Therefore it is difficult to make score-based inferences about a student's mastery of a general subject such as science based on the results of one or two performance assessments.

Because of the aforementioned limitation of breadth of scope of performance assessments, the best approach to standards-based district-wide assessment is to combine performance tasks with multiple-choice items. This approach allows districts to gain thorough knowledge about performance on critical standards while providing basic information about knowledge attainment on the remaining set of standards. By ensuring all standards are assessed, this approach helps emphasize that all standards are important.

Another assessment component used in standards-based systems is embedded assessment, which is the use of assessment tasks during instruction that are similar to those that will be administered during the district-wide assessment. This component of the assessment provides students with practice and also gives teachers a clear understanding of students' skill levels and where instruction could be targeted.

Inclusion of Students With Special Needs

As Vanderwood, McGrew, and Ysseldyke (1998) point out, students with disabilities are often not included in large-scale assessment at national, state, and district levels. Additionally, these same students are not included during the development and norming of many tests (Salvia & Ysselydke, 1998). By using performance-based tasks, standards-based assessment systems should be able to include more students with disabilities than traditional standardized norm-referenced assessment. In turn, the results should give teachers, administrators, and policy makers a more complete picture of educational performance of our student population. Given the push in the Individuals with Disabilities Education Act of 1997 (IDEA 97) to connect special education to the general education curriculum, it is critical that students with disabilities are considered and involved in the development of district-wide standards-based assessment.

For those students who are unable to participate in the standards-based district-wide assessment, IDEA 97 requires that they must be tested with an alternate assessment. Most states provide an alternate assessment that can in some places be used to be an alternate for the district assessment as well. In situations where an alternate assessment is not available, best practice in alternate assessment is to base the assessment upon the district standards to the greatest extent possible. The form and delivery of the assessment may be different than the assessment offered to other students, but the source of the expectations for performance should continue to be the district standards.

Reporting

One of the challenges in developing standards-based assessment is creating the performance standards that allow users to know how well students are performing. In essence, cut scores must be created to separate each proficiency level. A typical set of proficiency levels includes Novice, Basic, Proficient, and Advanced Proficient. Test developers must decide at what point do students move from being Basic to Proficient or Proficient to Advanced Proficient. Hansche (1998) argues that although there is not one right way to develop performance standards, test users should not create cut scores from norm-referenced tests and label them proficiency levels and suggest that the test is now standards-based. Just changing how test results are reported does not align the assessment with the standards nor with instruction. Psychologists who are asked to help develop performance standards should refer to Hansche (1998) or other more detailed references.

In a standards-based assessment system, scores are reported and goals are set differently than in standardized norm referenced assessment. As shown in Table 1, in a typical standards-based model, the percentage of students in each proficiency level is presented versus an average score for a building or district. By examining the percent of students in categories, districts can set goals such as having at least 50 percent of the district at Proficient or higher level. This method also allows consumers to gain a better picture of the change taking place within a district.

BEST PRACTICES IN AREA

This section details a mythical district that integrates all of the best practices mentioned and also provides

Table 1. Sample reporting format for a standards-based district-wide assessment: Percent of students at each proficiency level

Content	*Novice*	*Basic*	*Proficient*	*Advanced proficient*
Reading	30%	20%	35%	15%
Mathematics	22%	38%	32%	8%
Science	10%	45%	25%	20%

suggestions for the use of standards-based assessment data for 3-year reviews, problem analysis, and progress monitoring. The differences between a standards-based system and a traditional system are significant throughout the system, but this case study will primarily focus on the connection between standards and assessment.

Case Study

A large urban district began standard-based reform in the late 1980s. District personnel formed standard-setting committees to identify what students should know and be able to do at particular grades for specific content areas. National and state documents were used as starting points for each of the academic domains, and community members were selected to be active participants. A special emphasis was placed on including district employees and community members who work with or parent students with disabilities to ensure the standards represent *all* students. After content standards were developed, many committees developed performance standards or benchmarks that identify what level of performance meets the standards. The first step in developing the performance standards was the creation of performance descriptors that corresponded to expectations for what students at the Novice, Basic, Proficient, and Advanced Proficient are expected to know and be able to do. The descriptors were created through a combination of expert opinion and expectations of the committee members.

Based on the descriptors, another committee reviewed commercially available assessment systems and commissioned teachers within the district to develop tasks that focused on critical standards. After almost 9 months of review and development, the committee created assessments that were a combination of performance tasks and multiple choice items for grades 4, 8, and 11. The committee selected these grades based on the state's requirement, but a plan was developed to extend to additional grades in following years. Based also on the state's expectations, the committee decided to administer the district assessment in the spring a few weeks before the state assessment.

At the same time that the assessment system was being developed, using the standards as the starting point, committees developed curricular frameworks that delineated what was to be taught and provided example activities or lessons to develop the skills targeted by the standards. The curriculum committee worked with the assessment committee to create embedded assessment tools that teachers could use throughout the year to help gauge student performance. These assessments were designed to require students to respond in the same format that is required on the district assessment.

Use of Standards-Based Assessment By School Psychologists

The 1997 amendments to IDEA encourage the use of assessments that include "information related to enabling the child to be involved in and progress in the general curriculum." Standards-based district-wide assessments are designed to directly address the extent to which a child is meeting district expectations that are then taught in the district's curriculum. Therefore, these tools appear to be an excellent source of information for 3-year reviews and intervention development and monitoring.

Rather than repeating the battery of commercial, norm-referenced tests that were used to initially qualify a student, school psychologists can use standards-based district-wide assessment to focus on improving the special education programs provided to students with disabilities. The National Association of School Psychologists (NASP) recommends that re-evaluations focus on (a) evaluating the effectiveness of the student's current placement, (b) planning services that allow the student to participate in the general education curriculum to the maximum extent possible, and (c) investigating changes in qualifications *only* if requested by a parent or if there is evidence that the current qualification is no longer valid (National Association of School Psychologists, 1995). Standards-based assessments can be extremely useful in investigating each of these issues.

The increased emphasis in IDEA 97 on alignment between special education programs and the general education curriculum suggests that re-evaluations should incorporate district standards-based assessments as much as possible. Students' performance, particularly their gains over time, on standards-based assessments will provide good information on how well their current program is preparing them to meet the district standards and the general education curricular expectations. The district standards-based assessments provide a yardstick by which all programs and their effectiveness may be measured. If a student continually fails to make progress on these measures, then the Individual Education Plan (IEP) team should closely scrutinize the student's past and present opportunity to learn the skills and knowledge assessed by these measures. For example, it may become apparent that a student is engaged in rote, remedial work such as completing work sheets rather than constructing written responses to prompts. Repeated poor performance on the writing performance assessment is predictable given the student's limited opportunity to practice and receive instruction and corrective feedback on writing essays. Reevaluations that focus on program quality may even uncover systemic problems such as a failure to provide standards-based curriculum materials or sufficient training to special education teachers.

Planning for students' future services may also be informed by standards-based assessments, particularly for students who participate directly in general education programs. Modifications to the standards-based assessments such as extended time, use of a spell checker or calculator, or allowing the student to respond verbally to prompts read aloud should be extended to curricular modifications that occur in general education. Furthermore, district assessments provide critical information that can indicate areas in which the special education students' skills are discrepant from those of his or her general education peers. Careful analysis of this discrepancy will suggest specific interventions or modifications that will be necessary for the student to be successful in general education. Furthermore, students' performance on the standards-based assessment will identify specific skills to be targeted by the IEP so that the student may meet the district performance standards for graduation.

In addition to providing information for 3-year reviews and IEP planning, school psychologists can use these assessments to help analyze referral concerns and monitor progress. A unique aspect of some standards-based district-wide assessment systems is the use of embedded assessment. As previously described, embedded assessment is intended to provide students with practice with the district testing format and help school staff identify student concerns. Given that embedded assessment is linked to the district standards, school psychologists can monitor a student's progress across the academic year. Many districts ask teachers to select specific standards and only use embedded assessment throughout the year on those specific standards. School psychologists should investigate whether embedded assessment exists for referral concerns that may be connected to standards that the district is not assessing throughout the year. Although generally many embedded assessment tools are based on a 4 or 6 point scoring rubric, a qualitative analysis of the student's work over time can be extremely useful for providing intervention and instructional recommendations.

Besides focusing on individual student results, school psychologists can use standards-based assessment data to evaluate the effectiveness of school- or district-based programs and courses. The data can help describe the impact of a new reading series or a new approach to math that teachers are using to teach problem solving. Although program evaluation is often not as obvious as individual student evaluations, school psychologists can have a significant impact on students by assisting in the design and interpretation of system wide data.

SUMMARY

Large-scale assessment is in the midst of significant reform and change. The change in assessment systems is caused by the desire to more closely align assessment with what is expected of students. Some authors suggest that traditional standardized norm-referenced testing can not provide the data necessary to help schools improve. Standards-based district-wide assessment starts with standards that inform instruction and are the core of assessment. Substantial effort is placed into ensuring the alignment between the standards, instruction, and assessment. Besides typically including more performance assessment than traditional standardized norm-referenced assessment, standards-based procedures also report scores differently and attempt to create a focus that is broader than examining the average score. The process of creating proficiency levels requires an understanding of what distinguishes each level, which can be determined through expert judgement and consensus building. Schools can use the proficiency levels to set goals, and in fact, to inform school report cards.

School psychologists need to know the characteristics of strong standards-based assessment systems and be able to use the data for multiple purposes. Of course, with any assessment system there are psychometric and practical limitations. Performance assessments are typically less reliable than traditional multiple-choice tests, but the performance tasks can often provide teachers with information that is valuable for instructional planning. Test developers should ensure that all standards are appropriately assessed, although more critical standards may be addressed more thoroughly with performance tasks or portfolio assessment. Standards-based assessment systems can be used to help inform initial and 3-year reports, as well as serve as source for problem analysis and progress monitoring.

School psychologists can play an active role in helping develop, administer, or interpret standards-based assessment data. Within a problem-solving context, standards serve as the expectations that are the starting point for defining the problem or concern. Standards-based district-wide assessment can provide information that is relevant for problem analysis and progress monitoring. The assessment data can also be useful for informing 3-year reviews and helping IEP teams develop goals. In some cases the standards-based assessment can be used as a means to monitor the IEP goal.

This seminal work about standards provides readers the necessary history and political scenery to understand the context of the standards movement. It is an essential source of information for those who want to be informed about standards-based reform.

19 Best Practices in Planning and Conducting Needs Assessment

Richard J. Nagle
University of South Carolina

OVERVIEW

Considerable attention has been given to the expanded role of the school psychologist to meet the demands of linking service delivery to school reform and restructuring initiatives (Knoff & Curtis, 1996; Romualdi & Sandoval, 1995). School psychologists can assume an active role in designing programs or services that meet the needs of children in their work setting. Needs assessment is a systematic process of collecting and analyzing data in order to identify needs and problems to be addressed in program planning, development, and modification. School professionals must develop clear and comprehensive goals that are responsive to the realities of the school and community. Since services should be those that are both required and desired, needs assessment serves as the foundation on which programs are formulated (Lewis & Lewis, 1983).

Definitional and Conceptual Issues in Needs Assessment

The most common model for identifying needs in the schools is the discrepancy between some current condition and some desired (or required) state (Kaufman & Zahn, 1993; McKillip, 1987). In comprehensive needs assessment, once these gaps or needs are identified, the evaluator must also identify and assess existing school and community services and other resources to meet those needs, develop priorities among identified needs, and determine which services should be maintained, altered, or newly developed.

A need also has been defined as a "value judgment that some group has a problem that can be solved" (McKillip, 1987, p. 10). In defining needs in this manner, McKillip (1987) underscores several important considerations for those who conduct needs assessments. First, since needs involve values it must be recognized that different people may perceive different needs for the same situation. It is also quite possible that those observing needs may differ from the person experiencing the need. It is not uncommon for service providers to differ from service recipients in reported needs. Second, since needs may emerge for a particular "group," this implies there is an environmental context that will require careful description to facilitate needs analysis. This is particularly important in identifying groups that may be "at-risk" for poor outcomes. Third, McKillip states that the definitional component of "problems" reflects an inadequate outcome that falls short of expectations. Last, recognition of a need implies a judgment that problems that are detected can be solved. Since problems may be created by multiple causes or factors, potential solutions must be judged by their probable efficacy in alleviating the problem, the general cost of the solution, and the feasibility and ease of implementation of the solution.

Bradshaw (1972) has developed four distinct conceptual approaches in defining and measuring need. These categories are labeled normative need, relative need, perceived need, and expressed need. This categorization is useful to needs assessment activities in that it offers multiple perspectives of need, as well as different but complementary approaches to comprehending need (Kettner, Moroney, & Martin, 1990).

A normative need implies the presence of some norm or standard, with need being evaluated against some standard. These standards are often set by experts, professional bodies, school boards, or governmental bureaus (Rothman & Gant, 1987). Normative expectations are particularly useful in program planning and involve areas where there is a lack of experience (McKillip, 1987). Although normative information may be advantageous in providing program planners with objective targets, a potential shortcoming with this approach is that norms or standards are subject to change.

Felt or perceived needs are what people think or perceive as their needs or expectations for service outcomes. Perceived needs are based on the presumption that individuals in the target population have insight into their own needs (McKillip, 1987). Nevertheless, program planners may discover ways in which services can be designed to be responsive to client needs. Unlike normative need where a single standard exists, with perceived need the standard changes with each respondent (Kettner et al., 1990). Thus, these data may be highly variable and individualistic. Once consumers are asked to report perceptions of their needs, expectations may be raised that program planners will implement programs that will meet their needs (Kettner et al., 1990).

An expressed need deals with the actual utilization of services. This approach provides an estimation of the percentage of people whose perception of need has been mobilized into action (Kettner et al., 1990). However not all people in need seek services. Since the main focus of expressed need involves the utilization of current services or programs, identifying only those services or programs can result in solutions that maintain the status quo (McKillip, 1987). Waiting lists, requests for services that do not exist, petitions, etc., are all indicators of expressed need.

Last, comparative or relative needs involve the comparison of one group with another. The disparity existing between the two groups is the criterion on which the existence and extent of need are established (Rothman & Gant, 1987). Unlike normative need, there is no standard benchmark but rather group comparisons. These comparisons could involve contrasts between elementary schools within the same school district or grade level differences within the same school building, with the revealed gaps between levels of services in these groups indicating need. Program planners who make group comparisons should be attentive to the unique sociocultural variables or environmental context among different groups to accurately explicate these differences.

As can be seen, all of these conceptualizations of need have distinctive features. In the following sections of this chapter, the reader will see that different methods of needs assessment emphasize certain conceptualizations of need. Given the limitations of each conceptual approach to need, multiple methods or techniques of needs assessment are often recommended to reduce bias in the identification of population needs.

Purposes of Needs Assessment for School Psychologists

The scope of a needs assessment can be very broad-based, such as at school district and/or community level, or much narrower in focus, such as at the school, grade, or department level. Despite the potential breadth of scope of needs assessment activities, there are several general purposes of needs assessment for school psychologists. As was previously discussed, needs assessment can serve as the foundation for program planning, development, and modification. Needs must be identified before they can be addressed by services. Needs assessment data may also provide information to decision-making bodies such as a school board to justify budgeting priorities. When a strong correspondence between allocation of money and other resources and needed services is observed, decision makers demonstrate strong accountability for their actions. Additionally, identified needs among a target population in a school district may justify funding requests for internal funding or external sources local, state, or federal grants. Furthermore, needs assessments may also be required as part of the funding request proposal.

Needs assessment can also be useful in promoting the professional development among school personnel. Training needs may be established and needs assessment information can aid in the design of staff development activities (i.e., inservice training) that are both relevant and appropriate to improving job functioning among school personnel.

Last, dissemination of needs assessment data may serve an important informative function with the schools and/or community. This can serve as the basis for school and/or community awareness of what the needs are and which courses of action decision makers are considering in their problem solving.

BASIC CONSIDERATIONS

School psychologists may become aware of problems in service delivery in a variety of different ways. Since the role of the school psychologist will vary considerably from school district to school district, they also will differ relative to their relationship with program planners. The conduct of needs assessments is broadly divided into three components: the planning, or pre-assessment phase; the data collection, or assessment phase; and the post-assessment, or dissemination of results phase.

Planning the Assessment Program

PRE-ASSESSMENT PHASE

One of the initial phases in conducting a needs assessment is to clarify the presenting problems or unsatisfactory state of affairs. According to Illback, Zins, Maher, and Greenberg (1990), these problem clarification activities are aimed at providing "systematic information to place the problem(s) in context and to assure that appropriate planning occurs based on a clear understanding of service needs" (p. 807). This contextual analysis provides initial data regarding the nature and scope of these problem(s). Methods that have been suggested in the literature to establish need include review of school documents, reports, and files, direct observations, and brief interviews with involved persons (Harrison, 1987; Illback et al., 1990). These interviews should be conducted with program planners, as well as a diverse sample of school personnel, to clarify the problem from different perspectives. These methods are used to determine what is already known about the needs of the system and to identify issues and major areas of concern (Witkin & Altschuld, 1995).

Another important dimension to the problem clarification phase is that it allows the school psychologist to estimate how receptive the school and/or community will be to change. The opportunity and commitment for program planning by key stakeholders must be present. Soriano (1995) stated that organizations undertaking needs assessments must carefully consider the changes they are willing and able to make based on the information obtained during the pre-assessment phase before new information is gathered. The initiation of needs assessment without the prior commitment to use data for planning purposes is a waste of time and resources and will likely result in conflict within the school (McKillip, 1998; Warheit, Bell, & Schwab, 1977).

ESTABLISHING A NEEDS ASSESSMENT TEAM

A needs assessment team is a working group that will be responsible for the planning, monitoring, and perhaps executing the needs assessment process. The size of group is dependent upon the nature and scope of the needs assessment effort, but usually not more than six people is a manageable size, particularly if the project is at the school level (National Urban League, 1983). Furthermore, it has been suggested that members of the needs assessment team be selected based on the criteria of familiarity and knowledge of the target population, community resources and institutions, and the organizational context in which the programs will operate (National Urban League, 1983).

The needs assessment team should appoint a director of the project. For purposes of this chapter, it is assumed a school psychologist will fill this role. Since this person will be required to oversee the entire project, he or she should have sufficient technical expertise and leadership skills to fulfill this function. The school psychologist is one of the few professionals in the school and most community agencies with measurement expertise and training in statistical and research methodology, evaluation, and testing procedures (Romualdi & Sandoval, 1995). Other members selected for the team should be individuals who work cooperatively in a group, are task oriented, are capable of making fair and objective decisions, and have a strong commitment for program planning in the area of demonstrated need (National Urban League, 1983).

Beyond personal characteristics, potential assessment team members should be considered from a variety of school and community institutions. This group may include students, teachers, parents, community leaders and decision makers, local university faculty, representatives from appropriate community agencies, school board members, school administrative level personnel, or principals. If the needs assessment is being conducted at the school level, then a representative from the Parent-Teacher Association or school advisory council should also be considered. The needs assessment team should have sufficient breadth of viewpoint to comprehend the problem and be able to assess the feasibility of different assessment approaches. The inclusion of members who are decision makers, such as principals for school-level assessments or school administrators/board members for district-level assessments, is necessary to build in commitment and political influence for program development recommendations based on the final needs assessment report. The needs assessment team may also recruit additional groups of stakeholders to aid in selected facets of the needs assessment if the workload is beyond the reasonable capabilities of the team.

Interest and commitment for the needs assessment may be high, but existing resources may be limited. Once the needs assessment team has been established, the scope of the needs assessment must be determined .The amount of resources available to conduct the project is an important determinant of the scope of the needs assessment. Practical considerations of budget and human resources will influence the method and level of information that can be gathered during the assessment process. At the same time, team members also need to evaluate the degree of technical expertise to carry out some of the tasks of the needs assessment. If none of the members has sufficient skills in research design, and data collection, and analysis, then the hiring of a consultant with these skills should be considered. Obviously, the hiring of consultants outside the school will require adequate financial resources. Alternatively, the assessment team may be able to recruit volunteers with these professional skills.

Frequently the school psychologist may be the only person available to conduct the needs assessment. In the absence of an assessment team, the school psychologist may solicit input from individuals using the same selection criteria used to choose members of the assessment team.

SELECTION OF METHODS

After the initial planning activities are completed, the assessment team must determine what information should be collected. Team members should specify critical issues to be studied and information that is necessary to understand them. The information to be gathered should be both quantitative (e.g., percentage of target group children not receiving a particular service) and qualitative (e.g., possible barriers to receiving such services). It has been suggested (National Urban League, 1983) that this information should be sufficiently specific to indicate the extent of the problems, influence on the problems, community resources available to deal with the problems, and hypotheses about potential solutions. The gathered information should not be so complex, however, that the assessment process becomes unmanageable, too time consuming, or beyond the resources or expertise available (National Urban League, 1983). If the assessment process becomes too burdensome in terms of time and energy, then it may delay or detract from program development and implementation activities.

Once the plan has been formulated, the committee should establish a timeline for completion of the needs assessment (Reviere & Carter, 1996). This time frame should span from planning activities to the dissemination of the results of the needs assessment. According to Reviere and Carter, a good plan should include how to cope with barriers that may emerge during the assessment process. When unexpected or difficult circumstances arise, needs assessors should be flexible and creative. While developed plans should be adhered to as closely as possible, those carrying out needs assessments may have to modify plans as necessary. A well-conceived plan maximizes the probability of quality information to be used in program planning.

BEST PRACTICES IN NEEDS ASSESSMENT

Once the pre-assessment phase is completed, the needs assessment process moves to the assessment phase, which involves data collection and analysis. There are a number of different commonly used methods to needs assessment. Each approach has its own set of advantages and disadvantages that will be addressed. Each method can be easily modified relative to the scope of the needs assessment (i.e., school level, school district level).

Resource (Program) Inventory

A resource inventory is a compilation of services available to the target group in a specific service area (McKillip, 1987, 1998). This information is typically gathered by surveying service providers in the local community and school district. The central aim of a resource inventory is to describe available services, with particular emphasis placed upon identifying who is providing services, the characteristics and eligibility criteria of clients receiving services, and the service capacity of the program. Programs are also characterized based on their geographical location and organizational setting.

Programs can also be described based on the utilization patterns of services offered by each program. The underlying assumption of this approach is that program participants are those in the population in need of services. Since utilization rates represent manifestations of problems that have already developed, they are not helpful in prevention planning (Rhodes & Jason, 1991). Since resource inventories detail programs that have already been implemented, conclusions based on data drawn from this method may provide a status quo, institutionalized orientation to program planning (McKillip, 1987).

An important outcome of a resource or program inventory is that it may reveal significant gaps in services as well as identify underutilized services. It may also identify services that were previously unknown to the needs assessment team (McKillip, 1998). Furthermore, it may discover that different agencies provide overlapping services. In times of limited resources and budgets within the schools, the reduction in the overlap of services will allow for the allocation of resources into other areas of need.

Resource inventories are generally quick and inexpensive to conduct and are commonly among the initial steps in a needs assessment. As we have seen, the resource inventory can provide certain levels of information for program planning. When considered alone, a resource inventory does not indicate need. Gaps in programming may exist because such services are not needed. For this reason, resource inventories should be supplemented with measures of the extent of the problem and potential demand for services (McKillip, 1987, 1998).

Social Indicators

The social indicators approach to needs assessment presumes that needs estimates can be inferred by considering selected social and demographic statistics that have been found to correlate highly with service utilization (Lewis & Lewis, 1983). These statistics are presumed to be "indicators" of need. Social indicators are particularly valuable in establishing "at-risk" populations.

Because many federal, state, and local agencies, including schools, are required to maintain statistical information (Illback et al., 1990), social indicator data are readily available through government publications summarizing census data and surveys. McKillip (1998) presents a comprehensive list of sources of social indicator data for the purposes of needs assessment. Key among these sources is the U.S. census data collected by the U.S. Bureau of the Census every 10 years. Currently, detailed demographic statistics of census data are available on CD-ROMs. Other useful sources of data mentioned by McKillip include the *Statistical Abstract of the United States*, the *State and Metropolitan Area Data Book*, and the *County and City Data Book*. All of these sources are published in book form and are available on CD-ROM (see McKillip, 1998, for more detailed information). Additionally, local governments, health organizations, schools, social services agencies, and law enforcement organizations may be important sources of indicator information. Depending on the problem area being addressed, information from these sources may include socioeconomic status, racial composition, educational levels, health status, housing patterns, family integration, prevalence of delinquency, suicide rates, school dropouts, drug and alcohol abuse, special class placements, achievement test information, and the like.

A distinct advantage of the social indicator analysis is that information is readily accessible and generally can be gathered inexpensively by those with limited research expertise or technical skills (Warheit et al., 1977). Advances in computer technology have made access to data sources even more efficient. Another advantage of the social indicator approach is that the local community or school district can be compared to other communities at the local, state, or national level. In very large school districts or in school districts in which individual schools serve very diverse populations, it may be very useful to compare schools on selected demographic, economic, educational, and social characteristics.

Despite the advantages of social indicator analyses, there are several limitations in this approach. Because this approach is inferential in nature, it assumes that certain social indicators are predictive of needs for services. To validate this assumption, substantial evidence based on the research literature and prior studies is essential. Data from large geographic areas may not pertain or generalize to smaller communities or rural areas of interest (Rhodes & Jason, 1991). Before rates can be compared, differences in population characteristics should be carefully considered. Although extensive indicator data are available, the form or extent of the assessment team's informational requirements may not be fully met. For example, the data you are interested in gathering about certain child characteristics is subdivided into age levels different than those you require. Can it be assumed that information for 6 to 16 year olds is a valid comparison with the 6 to 12 year olds in an elementary school?

School psychologists who use the social indicator approach to needs assessment must be vigilant to population shifts that may occur in the schools they serve. While social indicator information is reported over a long time interval, it is possible that some communities may undergo very rapid changes. For this reason, the initiation of an indicator analysis can provide baseline data on school or school district demographics characteristics to monitor change and help guide future needs assessment programs.

Surveys

Surveys are the most commonly used needs assessment methods. Surveys are very flexible in format and can be conducted as face-to-face interviews, phone interviews, or questionnaires with a wide range of respondents.

SURVEY METHODS

School psychologists interested in using surveys to assess needs must determine which method is most appropriate for their purposes. The selection of which methodology to choose is generally based on the intended scope of the needs assessment, the technical expertise available to conduct the survey, and the time and resources needed to complete the project.

If the number of persons to be surveyed is relatively small, then interviews are probably the most efficient means of gathering information. Therefore, needs assessments conducted at the school level usually lend themselves to the interview format. The success of interviews is largely a function of the skillfulness of the interviewer. The interviewer must be able to establish trust and convey empathy in order for the respondent to answer questions without feeling self-conscious or suspicious. Additionally, the interviewer must be able to keep the respondent focused on subjects pertinent to the needs assessment. If skilled interviewers are not available, then considerable time and expense can be incurred for training. Interviews provide in-depth information (Kaman, 1986); that is, a broad range of topics can be covered, including demographic characteristics, needs, feelings, desires, and solutions to the problems the respondent is experiencing. The interview also allows the opportunity to explicate questions and to probe ambiguous answers given by the respondent. Interviews are particularly well suited in surveying the needs of marginal individuals (McKillip, 1987).

There are several advantages and disadvantages in the use of interviews. Interviews can be very time consuming and expensive, and do not lend themselves to sampling large numbers of respondents. Given the cost of face-to-face interviews, phone interviews may be a reasonable alternative. Conducting phone interviews tends to be faster, but, generally speaking, establishing rapport tends to be more difficult. Research also indicates that the rate of refusal to participate is higher with phone interviews than with personal interviews (Warheit et al., 1977). Phone interviews may be the method of choice when interviews need to be conducted over a geographically dispersed region. In this instance, traveling expenses may make face-to-face interviews prohibitive. All of these issues have different levels of importance depending on whether the school psychologist conducts interviews at the school, school district, or community level.

Questionnaires are generally the preferred survey method when large numbers of respondents are required. If the items are highly structured, then the data are easily quantifiable. The development of an effective questionnaire requires a certain degree of technical expertise. There are a number of important considerations in writing questionnaire items. A basic assumption is that the questions will be understandable, elicit the desired information, and motivate respondents to participate. Several sources (Edwards & Thomas, 1993; Fowler, 1993; McKillip, 1987, 1998; Soriano, 1995) provide excellent guidelines on writing and formatting questionnaire items. Since it is beyond the scope of this chapter to provide an in-depth description of questionnaire construction, the reader is referred to these references. Some of the central concerns in questionnaire construction deal with assuring an appropriate readability level of items for the respondents, controlling for social desirability of responding, selection of open- versus closed-ended questions, and the use of ranking versus rating questions (McKillip, 1987).

Once items have been written, the next step should be to pretest or pilot the items. This is usually accomplished by asking a small group from the proposed sample to complete the questionnaire. After this has been completed, respondents are asked to critique questions and wordings to determine whether questions are providing the information for which they were intended. Failure to undertake item piloting may result in wasted time and resources. Poorly written and designed questions will also result in decreased response rates.

Questionnaires have a number of disadvantages. They can be quite costly when reproduction, transportation, telephone, and postage expenses are considered. Generally, respondent turnaround time is slow so that a significant amount of time may elapse before the completed survey is received. If the response rate is low, then considerable time and effort will be spent in follow-up aimed at increasing questionnaire completion.

Whether or not interviews or questionnaires are selected as the survey method, an important methodological concern involves sampling. When the objective is to estimate the frequency of need in the general population, a representative sample of that population is required. In instances where information about a specific subgroup is required, *purposive sampling* is the methodology of choice (McKillip, 1987).

KEY INFORMANTS AS RESPONDENTS

Key informants are presumed to be knowledgeable about the problem under consideration. It is assumed that because of the nature of their work or position in the school or community, they will have a good understanding of the needs of the target population. The assessment team makes the selection of the key informants. The scope of the needs assessment and the perceived problem area will help identify who are the key informants. For community-based needs assessments, individuals may be selected from the areas of public office, welfare and social service, law enforcement, religion, health, mental health, and education. Needs assessments at the school and school district level may include school administrators, principals, department coordinators, guidance counselors, school psychologists, special education teachers, nurses, or regular education teachers.

In initiating the key informant approach, the assessment steering committee should construct an interview schedule or questionnaire that permits those conducting the survey to obtain comparable data from each of the informants (Warheit et al., 1977). The committee should also select a single method of data collection. The most frequently used technique is the personal interview since it permits face-to-face contact, an open exchange of ideas, and has the best response rate (Warheit et al., 1977). Questionnaires and phone interviews, which result in lower response rates, can also be used effectively.

If the key informant approach is well planned and a diverse sample of key informants is used, then the needs assessment can result in a comprehensive impression of the needs of the school or community. The key informant approach has many advantages:

1. It is generally simple and inexpensive to conduct.
2. Assessment is based on professional judgment and actual experience with the problem (National Urban League, 1983).
3. Because many school personnel and community agencies are involved, these interactions can serve as the groundwork for cooperation and the development of coalitions between these agencies or groups.
4. It serves as the basis for effective program planning by creating organizational readiness for change and support initiatives in program development (Illback et al., 1990).

The key informant approach allows for the input of many people with different perceptions of the problem situation. However, key informants may be biased since their views are impressionistic and tend to see needs through their organizational perspective. Key informants may be unaware of some of the needs of those they serve or may not comprehend the needs of those who are unserved or underserved. It is for this reason that those who use the key informant approach should evaluate the adequacy of the number and type of informants used.

While the key informant approach has some inherent problems, it can be a valuable first step in the needs assessment process. It can help narrow the focus of the assessment by assuring that appropriate group meetings, questionnaires, and social indicator approaches are designed (Lewis & Lewis, 1983).

CLIENT/COMMUNITY RESPONDENTS

Survey methods can be conducted on a specified sample or the entire population. Information gathered in a school-based or district-based survey can provide valuable information regarding the (a) frequency of the problem or need, (b) demand for available services in the system, (c) client view points of the problem and needed services, and (d) acceptability of solutions to the problem. The most important advantage of this approach is that it *directly* assesses the problems and needs of the sample surveyed. Thus, the client/community survey can locate specific individuals or groups in need and determine the type of services required and desired by the population (Balacki, 1988). Demographic and other characteristics of the population in need can also be determined.

When surveys are conducted at the client/community level, they can raise expectations that schools will address the problem area. The survey process can be reactive in a positive way by marshalling support for program initiatives by the various groups of stakeholders.

Surveys at the client/community level can be quite costly and therefore are not cost effective to use when every new program or service initiative is being considered (Lewis & Lewis, 1983). It is probably best justified for the purpose of cyclical reassessment of changing schools needs. Appropriate sampling techniques can reduce costs. The main limitation encountered with client/community surveys is that they may lack a broad-based perspective of problem or need (National Urban League, 1983).

Structured Groups

Structured groups provide a supplement and alternative methodology to other needs assessment approaches already reviewed in this chapter. Structured groups can be the most "active and informative" approaches to needs assessment since they involve people in systematic problem analysis and discussion (Illback et al., 1990). Focus groups, nominal group technique, Delphi technique, and community forums will be discussed.

FOCUS GROUPS

Focus group methodology is a commonly used qualitative research approach used for exploratory or hypothesis generation, and confirmation of results from other needs assessment approaches. Focus groups are guided discussions intended to yield information on specific topics relating to feelings and beliefs about needs from a selected population (Sussman, Barton, Dent, Stacy, & Stag, 1991).

Focus groups are lead by a well-trained facilitator knowledgeable about the problem under study. To begin, the group is usually asked broad, open-ended questions about the problem with questions becoming more specific. The size of focus groups is usually 6–10 people. Homogeneous grouping is essential to allow free interaction among group members (McKillip, 1987). The criteria for selecting members (i.e., age, ethnicity) should be determined by the objectives of the study; however, several groups with varied characteristics may be involved to learn more about subgroups in the population (Ward, Bertrand, & Brown, 1991).

Focus groups may be viewed as being quite similar to open-ended interviews. Research, however, indicates that focus groups are frequently superior to individual interviews because of the "synergistic group effect" that results in more identified needs and solutions (Sussman et al., 1991). Focus groups are frequently used in conjunction with other needs assessment methods. Focus groups are useful in helping explicate differences between professional (key informant) and target audiences (clients/community members). Many needs assessors use focus groups to aid in the construction of questionnaires by identifying issues to be addressed in the survey and to determine terminology and phrases used by the target population to describe their needs and solutions to those needs. Focus groups can also be used to gather responses to conclusions generated from other needs assessment methodologies. This latter use may also lead to the production of solutions to the identified areas of need.

NOMINAL GROUP TECHNIQUE

The nominal group technique (NGT) was developed by Delbecq and Van deVen (1971) to overcome the common problems of group dynamics including domination of talking high status group members, non-involvement of reticent members, evaluation of ideas impeding idea generation, and group tendencies to get "off-task" from the agenda (McKillip, 1987). The NGT was designed to give individuals with disparate interests, capabilities, information, or influence more equity in the decision-making and priority-setting process (Lauffer, 1982). The term "nominal" describes the process of bringing groups together but minimizing verbal communication (Miller & Hustedde, 1987).

The NGT requires a well-trained group leader or facilitator. The group can be composed of key informants, clients, teachers, students, or service providers (McKillip, 1987). Although there are a number of variants in the NGT, most involve the following steps (Frankel, 1987; Miller & Husteede, 1987):

1. Facilitator of group presents a problem or question that is clearly defined (e.g., *How can we prevent school violence?*).

2. Each group member is asked to write down independently and silently as many solutions on a piece of paper or index cards. At this point, no discussion is permitted.

3. Each group member presents one solution or idea, one at a time in a round robin fashion. The facilitator records each idea on a flip chart until all are recorded.

4. After all solutions are recorded, they are clarified and evaluated through discussion.

5. Group members are asked to either secretly rate each proposed solution or to rank order their top five choices.

6. Ratings are tabulated and a summary of the results is presented.

7. If clear choices and/or priorities result from the vote, then the NGT is complete. In the event of no clear choices, additional clarification, discussion, and voting are undertaken until a clear choice is obtained.

8. The cycle is repeated for each problem or solution area.

The priorities established by the group may not be accepted by others in the school or community. To minimize this possibility, the needs assessor should develop a plan that has adequate representation among subgroups in the school or community.

DELPHI TECHNIQUE

The Delphi technique was developed to obtain group opinion from experts or individuals with exceptional knowledge about a particular subject area. This technique was developed at the Rand Corporation in the early 1950s to solicit opinion from military officials regarding the number of bombs needed in the event of war (Miller & Hustedde, 1987). Although educational decision making does not deal with such dire issues, the Delphi technique has been used successfully in school program planning activities. Recently, Jeffery, Hache, and Lehr (1995) adapted the Delphi method by using groups of children and parents, in addition to experts, to determine career counseling needs of children.

The Delphi technique typically starts with the assessment team determining which needs will be assessed, who will participate in the process, and how the information will be used. Based on the domains to be assessed, a questionnaire is developed and sent to a panel of experts.

The Delphi technique elicits expert opinion through the use of successive questionnaires administered to individual "panelists," selected on the basis of their expert knowledge or opinion (Lauffer, 1982). The process is designed to forecast or predict events when inadequate information exists. The format of the Delphi method is quite variable relative to the number of questionnaires sent to the panel. For most school applications, three questionnaires are probably adequate if using a panel of 8–12 experts.

Miller and Hustedde (1987) have outlined the basic steps in having panelists complete the series of questionnaires. In the first questionnaire, respondents are asked to answer questions regarding a problem situation. The questionnaire is returned to the needs assessment team and the distribution of responses is summarized. This summary then serves as the basis of the second questionnaire. Panelists are sent the second questionnaire and are requested to rank their concerns, to agree or disagree with the central tendencies of the group, and to clarify their judgments. The goal of the second questionnaire is to portray agreements and disagreements in priorities. A third questionnaire is then mailed asking respondents to reassess prior answers and to clarify their ratings relative to the group. They are again asked to vote by ranking the items listed on the questionnaire. This process is considered complete when there is general agreement among panelists. In the event of substantial differences among panelists, the questionnaire refinement-feedback cycle is continued. The central aim of the Delphi technique is to clarify problems and needs, not reach group consensus. Once the process is complete, respondents should be provided with a final report.

The Delphi technique is usually blended with other needs assessment techniques. It can be effectively used to avoid confrontation when severe disagreement is likely to emerge among experts (Lauffer, 1982). This technique may also be a cost-effective way of gathering expert information by avoiding the high cost of travel.

The Delphi technique requires that respondents have well-developed writing skills as well as a high level of motivation because no facilitator is present to help stimulate responses (Miller & Hustedde, 1987). Although the length of time to conduct a Delphi panel will vary as a function of the number of questionnaire mailings, it typically takes about 2 months to complete the process.

COMMUNITY FORUM

The community forum is similar to a town meeting in which the views and opinions of community members about their needs and problems are gathered. The community forum is appealing because it is generally easy to arrange and can be conducted inexpensively. The community forum can be easily adapted to the scope of the needs assessment in the schools. If the scope of the assessment is at the school level, then the forum can be held at an individual school while a district-wide needs assessment may involve a sample of schools or all schools within a given district.

To enhance the effectiveness of a community forum, a certain degree of planning is required. First, the needs assessment planning team should prepare questions designed to structure the meeting around the issues and, at the same time, provide sufficient flexibility to allow for spontaneous comments and candor among the participants (Warheit et al., 1977). The meeting should be highly publicized through advertising and the media and held at a convenient time and accessible location, because it is essential that a representative sample of the community attend. Early evening meetings at the local school in the community member's attendance area fit these criteria.

A leader for the forum should be appointed by the needs assessment team. This individual should have sufficient skills to keep the audience discussion on track. The leader must clearly state the purpose of the forum and explain any ground rules that will be used, such as time limits on talking by participants. In the event of very large turnouts for the forum, it may be necessary to divide the groups into smaller sections to facilitate discussion. Obviously, in these instances, several group leaders will be necessary. A person from the needs assessment team should also be present to record the proceedings of the meeting. The group leader may also wish to take a vote on priorities and concerns. A sign-up sheet for all participants should be used so that follow-up mailings can be sent to those attending the meeting.

The advantages and disadvantages of the community forum approach have been discussed extensively by several authors (Lewis & Lewis, 1983; McKillip, 1987, 1998; Warheit et al., 1977). The community forum is easy to conduct, quick, and cost effective. The community forum allows for input from many segments of the community. The needs assessor may, in fact, become aware of some highly unique or unanticipated needs when the source of information is directly from potential service recipients. The community forum builds rapport and trust with the community and can enhance community members' commitment to program planning. It also identifies citizens who may be valuable resources for the later implementation of programs.

The validity of data gathered from a community forum will largely be a function of the representativeness of the group. Only a partial view of the community's needs or problems will be portrayed if the group is not representative of the general community. It is quite common for community members with severe problems or impairment not to attend a community forum. The forum leader must keep participants focused on the agenda, or else the meeting will degenerate into a gripe and grievance session. The forum leader must also avoid the meeting becoming controlled by special interest groups who wish to espouse their viewpoints, at the expense of not allowing others to offer opposing or different viewpoints. Similar to other needs assessment methods, the community forum raises expectations that something will be done to solve problems or to satisfy unmet needs.

The community forum is frequently used in needs assessment activities in the schools and is commonly used in conjunction with questionnaires to assess the "believed" needs of the community. The community forum approach is impressionistic and assumes that citizens are aware of and knowledgeable about their own problems and needs.

Selection of Needs Assessment Methods

As this chapter illustrates, needs assessment methods vary considerably in terms of their comprehensiveness, cost, and time necessary to complete the project. Some believe that cost and time should be held to a minimum so as not to interfere with other goals in the program planning process (Hobbs, 1987; Steadham, 1989). In performing needs assessments, no component is more important than the clear specification of the purpose and what you wish to accomplish in the needs assessment. The purpose and who you wish to influence are the most central criteria in choosing methods (Hobbs, 1987). There are a number of additional criteria to consider when choosing a needs assessment method. These include the resources required and available for needs assessment activities, the skills of the needs assessment team, characteristics of the client system, preferred methods of the decision makers, and the allowable time frame for the needs assessment project (Steadham, 1989).

Since all needs assessment methods have inherent strengths and limitations, many needs assessors have advocated the use of multiple methods. By adopting this strategy, the potential limitations of one approach can be minimized by the use of an additional, complementary method. Multiple activities will also help estimate the reliability and validity of the results of the needs assessment. Thus, the use of multiple methods in the needs assessment will increase accuracy and decrease bias with the final results (Jeffery et al., 1995).

Communication of Needs Assessment Findings

Once the needs assessment data are collected and analyzed, the post-assessment phase begins. A successful needs assessment provides information, via reliable and valid methods, that will be used for program planning, development, and modification (Aponte, 1983). The effective communication of the results of the needs assessment to decision makers is important because it will determine if the findings are used for program planning (McKillip, 1987). Decision makers will act upon needs assessment information only when they can understand the findings and see a clear connection between the needs assessment results and program planning. The needs assessment team must devise a plan for addressing how to communicate the findings to various audiences and how to make the results as meaningful as possible (Carter, 1996). According to Carter, the most common and effective means of communicating findings is the written final report.

The scope and framework of the final report of the needs assessment depends on the audience to be addressed. The communication must fit audience interests, keeping in mind that they are busy and often unsophisticated about research methodology (McKillip, 1987). Modifications in the report may be necessary in instances where the needs assessor will report the findings to several audiences with divergent interests. While needs assessors focus on the results of the project, program planners are concerned with the organizational consequences of their decisions (Aponte, 1983). The findings should be reported to correspond to the questions raised by the decision makers who most likely commissioned the needs assessment. Equally important is the timely presentation of the needs assessment results. If too much time has elapsed in the process of conducting the needs assessment, then the final report may include outdated information or issues that are no longer a priority with decision makers.

The findings of the needs assessment can be presented in written and/or oral form. Warheit et al. (1977) and Carter (1996) have suggested the following outline for the needs assessment report:

1. Executive Summary
2. Statement of Problem
3. Historical Background
4. Methods
5. Findings
6. Recommendations

The written report should provide information about the study from its inception to completion (Carter, 1996). Written reports should be as concise as possible and should not be overly lengthy. Reports should be free of jargon or technical terms and provide only necessary information that will facilitate decision making. Poor grammar, typographical errors, and the like should be avoided because they will detract from the credibility of the report. The visual display of the findings also tends to facilitate clarity and understanding.

If an oral presentation is used, then the needs assessment team must be sure that the presenter will be articulate, knowledgeable, and enthusiastic about the findings. Oral presentations should be supplemented with handouts of the major findings of the needs assessment. Overheads or slides are also a useful means of avoiding information overload by audience members. A distinct advantage of the oral presentation is that it allows for personal contact with the exchange of information and occurs at a specified time (McKillip, 1987). Written and oral briefings are typically combined in needs assessment activities.

Many needs assessment efforts fail to plan adequately for the post-assessment phase. Amodeo and Gal (1997) lamented the failure of their organization to utilize the findings of their needs assessment in program implementation. They attributed the lack of utilization of their findings to a variety of factors that could have been avoided. First, they felt that too much time was spent in data collection, and as a consequence decision makers felt a sense of urgency to implement programs without waiting for the needs assessment findings. Second, many stakeholders in the organization viewed the needs assessment as an end in itself and failed to see a connection between the results and recommendations for change in program planning. Third, insufficient time was provided to decision makers to reflect upon the findings of the needs assessment report. In their case study, the decision makers had not had ample opportunity to review the written report before its oral presentation. This latter finding underscores the importance of keeping the decision makers apprised of the progress of the needs assessment through the use of interim reports from the planning team. Communication with administrators also informs the needs assessment team of organizational changes within the school or agency that may affect conduct and focus of the needs assessment.

The likelihood that the school or organization accepts the recommendations generated by the needs assessment report will be enhanced if the proposed changes are based on factual data from the needs assessment, are rank ordered by time-cost benefits, are achievable, reflect the best-interests of the school, and have the highest potential for resolving the need (Warheit et al., 1977). Once priorities are established by the needs assessment team and/or decision makers, action plans should be developed that require commitment from leaders within the organization (Altschuld & Witkin, 2000). Thus, the responsibilities of planning activities are shifted to stakeholders within the organization.

SUMMARY

This chapter sought to describe the process of how to plan and conduct needs assessment in schools. A number of different needs assessment methodologies were explored, with the strengths and limitations for each approach discussed. Needs assessment serves as the foundation on which programs in the schools are designed. As schools become increasingly involved in reform and restructuring activities, school psychologists will need system-based skills such as needs assessment. While school psychologists have substantial skills in measurement and research methodology, few have received training in needs assessment. Clearly, training programs will need to prepare students in this area to meet the changing role responsibilities of many school psychologists (Romualdi & Sandoval, 1995). Depending on the resources available in the school districts in which they work, school psychologists can play an active role in contributing their unique skills to needs assessment activities.

ANNOTATED BIBLIOGRAPHY

Edmunds, H. (1999). *The focus group research handbook.* Chicago: NTC Business Books/American Marketing Association.
This book provides a comprehensive overview of focus groups, including how to conduct groups, how to recruit participants, how to manage special subgroups, and how to report results. The appendices are particularly useful and provide samples of focus group screener questionnaires, discussion guides, and executive summary reports.

Fowler, F. J. (1993). *Survey research methods* (2nd ed.). Newbury Park, CA: Sage.
This book is among the best sources available on how-to-do surveys. There are particularly helpful chapters on sampling, item writing, interview methods, data analysis, and the ethical issues involved in survey research. This is an indispensable source for school psychologists interested in using surveys for research or program development.

Harvey, T. R. (1990). *Checklist for change: A pragmatic approach to creating and controlling change.* Boston: Allyn & Bacon.
This is an easy-to-read book dealing with the problems associated with organizational change. The author provides a step-by-step analysis of facilitating change with particular emphasis on how to overcome resistance to change and how to institutionalize change. The book contains many useful forms to evaluate the various steps in the change process.

Lauffer, A. (1982). *Assessment tools for practitioners, managers, and trainers.* Beverly Hills, CA: Sage.
This book was designed to acquaint professionals with the use of various structured group methods in needs assessment activities. Chapter 4 provides an excellent overview and case study of the nominal group method.

Chapter 5 discusses the Delphi method and presents several actual applications of this method.

National Urban League. (1983). *A guide for developing non-instructional programs*. New York: Author. (ERIC Document Reproduction Service No. ED 272 597).

This reference provides an excellent step-by-step guide in designing school programs. It includes major sections on needs assessment program planning, program implementation, and program evaluation. The authors, using their experiences with *Follow Through* programs, provide an actual case study on program planning.

Soriano, F. (1995). *Conducting needs assessments: A multidisciplinary approach*. Thousand Oaks, CA: Sage.

A concise guide to conducting needs assessments. The chapters on survey construction and sampling are particularly helpful. An appendix includes a needs assessment guide with a checklist of steps aimed at professionals with little experience in needs assessment activities.

Warheit, G. J., Bell, R. A, & Schwab, J. J. (1977). *Needs assessment approaches: Concepts and methods* (Publication No. ADM-77-472). Washington, DC: Department of Health, Education, and Welfare.

This publication continues to be one of the key sources on how to conduct needs assessments. The authors, using a community emphasis, provide many practical suggestions including how to form a team, select methods, construct questionnaires, do sampling, and supervise a needs assessment team. This book has stood the test of time and serves as an excellent introduction to needs assessment.

20 Best Practices in Working in Full-Service Schools

Jayne E. Bucy, Adena B. Meyers, and Mark E. Swerdlik
Illinois State University

OVERVIEW

As we begin the twenty-first century, school-age children and adolescents face significant challenges to their physical, academic, social, and emotional development (Paavola et. al, 1995). A variety of risk factors to the healthy development of this age group are increasing (Minke & Bear, 1997; U.S. Department of Heath and Human Services, 1999). These biological risk factors include prenatal damage from exposure to alcohol, illegal drugs, and tobacco; low birth weight; difficult temperament; or an inherited predisposition to a mental disorder. Environmental risk factors include such factors as poverty and deprivation; abuse and neglect, parental mental health disorders, and exposure to traumatic events; and unsatisfactory parental relationships owing in part to an increasing divorce rate. The resulting single parent homes, typically headed by women, are the most vulnerable socioeconomically. An alarming increase in the death rate among young people ages 10–24 owing to brain injury from automobile accidents, homicide, suicide, and HIV-AIDS also challenge the healthy development of our children and adolescents.

A number of stressors also influence the daily lives of our students and challenge their healthy development. These stressors include changes in family work patterns with the increasing number of two-parent families in which both parents are employed outside of the home, and the large number of parents who are teenagers themselves. Young people also face the more common stressors of reading difficulties, low achievement, aggression, bullying, fears, peer rejection, social skill deficits, and loneliness. Extensive national publicity has highlighted the deadly violence in our schools, which adds to the stress of students. Also, many students engage in binge drinking and unsafe sex, putting themselves at risk of developing serious health problems.

Many of our students have no health care because their parents are uninsured, yet these stressors and risk factors exist for them. There is a strong link between education and health: A student who is unhealthy will not benefit from even our best schooling. Many of the health problems noted above (e.g., HIV-AIDS, suicide), have behavioral causes. The "cures" for these illnesses rest with education; that is, teaching people the necessary skills to cope successfully with stressors both now and for the future (see Gutkin, 1995; Swerdlik, Reeder, & Bucy, 1999)

The consequences of these risk factors and stressors are seen in the statistics related to mental disorders in children and adolescents. Up to 21% of children and adolescents, aged 9– 17, have a diagnosable mental or addictive disorder associated with at least minimum impairment. Roughly 4 million children and adolescents suffer from a major mental illness that results in significant impact at home, at school, and with peers (U.S. Department of Heath and Human Services, 1999). On the basis of these data, it is more important than ever to provide comprehensive and integrated educational, mental health, medical, and social services.

The full-service school (FSS) concept represents a convenient service delivery system for students and their families to access needed intervention services,

288

provide prevention programs, and facilitate learning for all students. In addition to meeting the medical and mental health care needs of children, FSSs have the potential to support the educational mission of schools. By providing services in a non-categorical manner, children's needs may be addressed holistically and without the gaps and overlaps frequently experienced with categorical programs (Adelman & Taylor, 1997; Flaherty, Weist, & Warner, 1996).

The call for integrated and comprehensive models of services delivery, including FSSs, has occurred at many levels. The federal government has advocated for integrated and comprehensive service delivery through a variety of legislative initiatives such as Healthy People 2000 of 1990 and the 1994 Goals 2000: Educate America Act, which encouraged high performance standards, academic achievement, and intervention based on many of the social and health-risk behaviors enumerated above. At the state level, legislation such as Healthy Start in California includes funding for comprehensive and integrated models of service delivery. A number of national organizations for physicians, nurses, teachers, social workers, guidance counselors, and psychologists (APA and NASP) are stressing the importance of comprehensive and integrated school health services (Reeder et al., 1997; Dwyer, 1996).

School psychologists, who are aware of the benefits and challenges of functioning in the unique service delivery system of the FSS, represent highly valued and unique contributing members of a FSS's professional services staff. The goal of this chapter is to provide information and resources to facilitate the school psychologists' entry into and effective functioning within a FSS.

BASIC CONSIDERATIONS

Elementary and secondary schools that integrate a variety of expanded services are referred to as FSSs. Dryfoos (1994, p.142) defines a FSS as one that "integrates educational, medical, social, and/or human services that are beneficial to meeting the needs of children and youth and their families on school grounds or in locations which are easily accessible." The ideal FSS has administrators, teachers, school counselors, social workers, school psychologists, physicians or nurse practitioners, and other professionals working together to provide one-stop service delivery for students and families (Drotar, 1993). Some FSS are further described as school-based (services offered on school grounds) while others may be school-linked (services offered nearby, though off-campus) (Reeder et al., 1997).

Since their initial inception, FSSs have rapidly increased in number and location. According to the National Survey of School-Based Health Centers (Making the Grade, 1999) less than 100 FSSs existed prior to 1980. By 1990 there were 200, and rapid increases in the 1990s resulted in an increase to 1157 by 1998. While FSSs were initially found in the northeast, they are now located in 45 states and the District of Columbia. Once concentrated in urban areas, FSSs are increasing rapidly in rural areas, accounting for as many as 26% of all centers. FSSs serve children of all ages, with the largest proportions in high schools (38%) and followed by elementary (33%) and middle schools (16%).

Roles for School Psychologists in FSS

Interventions for mental health issues is the most common service provided by FSSs (Making the Grade, 1999), with a quarter of all visits resulting in a mental health diagnosis. Despite this, school psychologists may not be called upon to address this area of concern. In a survey of full service schools, Bucy et al. (1999) found that school psychologists often play a limited role in providing mental health services and are not included as clinic staff. Instead, mental health services are offered by social workers, clinical psychologists, and psychiatrists.

A variety of specific roles and functions have been described for school psychologists working within FSSs. Reeder et al. (1997) note that school psychologists may function as leaders or members of interdisciplinary teams or as university-based consultants. Others (e.g., Adelman & Taylor, 1993; Talley, Short, & Kolbe, 1995) have described a number of direct and indirect services that school psychologists and other mental health professionals can provide within the FSS context. These include relatively traditional activities such as psychological and educational assessment and intervention planning. In addition, there are new roles such as assisting with the creation of developmentally appropriate health education curricula; designing and implementing new prevention programs relevant to medical, mental health, or educational objectives; securing funds for expanded services to students and families; and a variety of professional development activities for school and agency staff.

The special characteristics of FSS settings require expanded conceptualizations of the roles of all relevant professionals, including school psychologists. Specifically, school psychologists working within FSS settings may find that their roles (a) address a range of physical and mental health issues; (b) emphasize preventive activities; (c) are more interdisciplinary and thus demand more collaboration with students, parents, community members, and other professionals; (d) include opportunities for program development and grant writing; and (e) involve a variety of basic and applied research activities.

EMPHASIS ON PHYSICAL HEALTH AND MENTAL HEALTH

In their efforts to meet the needs of children and families in a comprehensive and holistic manner, FSS settings typically offer an expanded array of health-related services. School psychologists can contribute to these efforts in a variety of important ways. For example, drawing upon recent advances in the fields of pediatric psychology, health psychology, and behavioral medicine, school psychologists might collaborate with medical personnel to address behavioral aspects of health problems including chronic pain, medication noncompliance, or stress-induced somatic complaints (Kubiszyn, 1999). They might also offer health promotion or stress management interventions to school staff or parents (Talley et al., 1995). Furthermore, school psychologists can collaborate with physicians, nurses, teachers, and parents in the development and implementation of evaluation protocols for psychopharmacological interventions (Brown, Dingle, & Landau, 1994).

Many school-based and school-linked clinics, originally established to provide medical and family planning services, have evolved to address mental health issues to a significant degree as well (Weist, 1999). This has occurred, in part, in response to student need. It is estimated that only 40% of children with serious emotional disturbance receive mental health services of any kind, and that many drop out of treatment prematurely (U.S. Department of Heath and Human Services, 1999). It is therefore not surprising that a large proportion of the students seeking services at school-based and school-linked clinics present with psychosocial concerns (Adelman & Taylor, 1999). As a result, school psychologists working in FSSs may be called on to help coordinate, supervise, or provide a range of mental health and counseling interventions. To meet the often overwhelming demand for mental health services that can arise in this context, group counseling, classroom-wide interventions, and large-scale prevention efforts are often warranted.

PREVENTIVE SERVICES

By linking health, educational, and social services, the FSS implicitly recognizes the multidirectional links among physical and mental health, behavior, and environmental factors. This perspective is consistent with a public health approach to service delivery, in which preventive services play a prominent role (Albee & Gullotta, 1997). Preventive interventions, particularly those that would be categorized as primary prevention (Caplan, 1964), differ from more traditional service delivery models in several important ways. First, whereas traditional health and mental health services are provided to people who are already experiencing symptoms or problems, primary prevention targets entire communities or populations. "Primary prevention is a community concept. It involves lowering the rates of new cases of mental disorder in a population over a certain period by counteracting harmful circumstances before they have had a chance to produce illness (Caplan, 1964, p. 26)." Second, preventive interventions seek to promote healthy outcomes as well as reduce unhealthy ones, acknowledging the role of protective factors and strengths as well as risk factors and deficits. Third, preventive interventions attempt to identify environmental causes and solutions to problems, instead of focusing exclusively on individual or intraorganismic factors. Finally, many preventive interventions emphasize the role of behavioral and emotional functioning in the development and maintenance of physical health problems.

Given these defining features of the primary prevention approach, it seems that school psychologists working in FSSs are ideally positioned to develop and implement preventive interventions. As school-based professionals, they have access to entire populations of school-age children, not only those who are experiencing symptoms or problems. They can use their knowledge of environmental risk and protective factors to develop effective interventions, and their position in a collaborative setting with links to families and communities may aid in their efforts to address these contextual factors. Additionally, school psychologists can apply knowledge of behavior change methods to help students reduce risky behaviors (such as unprotected sex, substance use, and violence) and increase healthy ones (such as nonviolent problem solving, assertive communication, and healthy diet and exercise habits). A variety of empirically supported preventive interventions addressing these and other medical, mental health, and educational concerns have been described elsewhere (e.g., Albee & Gullotta, 1997; Minke & Bear, 2000).

COLLABORATION

By definition, FSS services are interdisciplinary. Professionals from various fields such as medicine, nursing, social work, special education, regular education, school counseling, and psychology must work together to provide truly coordinated services to children and families. Adelman & Taylor (1999) describe this model of integrated and comprehensive service delivery as the generalist approach, in contrast with the more typical problem-specific and discipline-focused specialist approach. Professionals working in FSSs will likely assume more of a generalist role than may be the norm in other settings. They must be prepared to collaborate with other professionals whose educational backgrounds, communication styles, service priorities, and ethical concerns are unfamiliar. Furthermore, in truly comprehensive FSS models, this collaboration must extend beyond other school-based professionals to include staff at off-site agencies, parents, and other members of the community. As Reeder et al. (1997) and others have pointed out, school psychologists may be able to use their consultation skills and knowledge of group process to help facilitate these collaborative relationships.

PROGRAM DEVELOPMENT AND GRANT WRITING

FSSs provide unique opportunities for school psychologists to participate in program development and innovation. This is especially true for school psychologists in leadership or administrative positions. Ideally, school psychologists would be involved in the development of school-based or school-linked services from the beginning (Reeder et al., 1997). Even within an existing FSS, the school psychologist might take on administrative and supervisory functions that involve creation of new programs or service delivery models. In order for such innovations to be implemented and maintained, school psychologists must be prepared to identify and pursue outside funding sources.

BASIC AND APPLIED RESEARCH

Although school psychologists, especially at the doctoral level, have extensive training in research design and methodology, survey results indicate that research endeavors comprise only a small fraction of practitioners' professional activities (Reschly & Wilson, 1995). However, school psychologists working in FSSs may be called upon to conduct applied research to monitor and improve the quality of services provided. These activities may include needs assessments to identify service priorities and available resources, as well as program evaluations to assess the processes, outcomes, and cost effectiveness of the services provided. Moreover, in this context of innovation, some school psychologists may be able to conduct the type of systematic, controlled research that Fairweather & Davidson (1986) describe as community experimentation. In this way, the theories behind various approaches to intervention and service delivery may be tested, and new knowledge about human development may be generated (Bronfenbrenner, 1977).

Challenges and Barriers

As school psychologists strive to fulfill these new role expectations and function optimally in FSSs, a number of obstacles and challenging situations are likely to arise. These include ethical dilemmas, role strain, reimbursement and funding concerns, community relations, and difficulties with the collaborative process itself.

ETHICAL DILEMMAS

Ethical dilemmas regarding such issues as confidentiality and informed consent are a source of ongoing challenge for school psychologists working in FSSs. Protection of client confidentiality becomes complicated in any integrated service delivery model, especially if multiple agencies are involved. School psychologists providing mental health services to students may feel pressure to share information about the course of counseling with teachers, guidance counselors, and other team members. Decisions about how much or even whether such information should be shared may be quite difficult. Additionally, when counseling services are provided within a school, client confidentiality can be jeopardized because of the small size of the client base. Students may quickly learn where the counseling office is, and may observe other students coming and going. In group counseling scenarios, group members may be acquainted with each other and with each other's friends outside of the group. In this context, confidentiality breaches by group members can be particularly detrimental and yet at the same time quite difficult to control. If third parties are billed for mental health services, then client confidentiality is further compromised.

Special attention must also be given to the procedures and policies for obtaining informed consent for mental health services provided in a FSS. In general, when health and/or mental health services are provided to minors, informed consent must be obtained from parents. Legally, there are some exceptions to this, such as counseling in crisis situations. Also, some states have laws allowing adolescents to consent to services on their own behalf. In situations in which informed consent is to be obtained, questions remain as to whether this consent must be active (i.e., requiring a signed permission form) as opposed to passive (i.e., informing parents of the services and allowing them to refuse). In the case of some school- or classroom-wide preventive interventions, the answer is unclear. It is even less clear in the case of children who are wards of the state, or with so-called *adolescents on their own* (Armbruster, Andrews, Couenhoven, & Blau, 1999) who may not have any contact with their parents. Evans (1999) argues that parental consent should be obtained for all school-based mental health services (even low-risk, preventive, school-wide interventions) and that active consent is preferable to passive consent. He acknowledges, however, that following these conservative guidelines will result in the denial of needed services to some troubled children.

ROLE STRAIN

In the effort to provide comprehensive services to all students, schools and practitioners may find themselves over extended. The move toward a generalist model of service delivery is appealing in many respects, and is more cost-effective than a fragmented specialist approach, but coordination alone cannot solve the problem of scarce resources. Schools often find that even after instituting FSS programs, many unmet student needs still exist. As Adelman and Taylor (1999) point out, "Even when one combines community and school assets, the total set of services in economically impoverished locales is woefully inadequate" (p. 146). At the level of the individual practitioner, the more flexible and expanded role opportunities in the FSS provide an exciting avenue for professional development, but can also be overwhelming, leading to feelings of stress and exhaustion. Depending on the practitioner's prior training and experience, the generalist approach may bring pressure to work outside of established areas of professional competence. Conflicts of interest may also arise owing to the assumption of multiple roles.

REIMBURSEMENT AND FUNDING ISSUES

The question of funding brings with it a number of potential problems and challenges as well. Carslon, Tharinger, Bricklin, DeMers, and Paavola (1996) point out that traditional, categorical funding mechanisms push services toward fragmentation, thus impeding efforts to coordinate services for children. Also, FSSs often experience the problem of "projectitis" (e.g., Adelman & Taylor, 1999), in which school or agency resources are allocated to specially funded projects, only to find that the projects are soon abandoned because the funding has run out. Many school-based and school-linked clinics are moving toward collaborations with Managed Care Organizations (MCOs), including Medicaid MCOs (Armbruster et al., 1999). While MCOs are potentially good sources of funding, these organizations have requirements related to credentialing and documentation that may be quite unfamiliar to school psychologists and other school-based professionals. Also, MCOs usually require information about diagnoses and treatment progress that raise confidentiality concerns, especially in the case of adolescent clients who may not want their parents to know about the services they are receiving.

COMMUNITY RELATIONS

An optimally functioning FSS must be supported by parents and other community members. Garnering such support may be difficult in communities where mental health services are regarded with suspicion or where parents already feel alienated from the educational system or from social and health service agencies. Unexamined cultural differences between FSS staff and community members may compound these problems. Even in communities where a majority of parents support the mission of the FSS, more marginalized groups, such as so-called difficult to reach parents, may be less supportive, indicating that the resources available through the FSS are not maximally effective for all intended recipients. In addition to the challenging task of forging positive relationships with parents, practitioners working within FSS may run into problems if the community as a whole, and community-based service agencies in particular, are not supportive. The relationship between school- and community-based service agencies must be thoughtfully and collaboratively negotiated.

THE CHALLENGE OF "TRUE" COLLABORATION

Many of the barriers and challenges that are unique to working in FSSs stem from the need to collaborate effectively with others. Minke (2000) describes true collaboration as a process that entails crossing traditional boundaries, sharing resources, and developing common goals. This is a tall order, especially among diverse professionals who are accustomed to a more specialized approach to service delivery. Minke argues that many school-based and school-linked services exemplify failed or incomplete efforts at true collaboration.

FSSs must be seen by teachers as more than pull-out programs that disrupt instructional time. Teachers are a source of referral for children experiencing difficulties in educational, social, familial, and medical areas. As stakeholders in the program, teachers must become actively involved in the development and implementation of FSSs. Many barriers exist to their full participation including weak links between teachers and FSS staff, differences in training levels (graduate versus undergraduate), disciplinary professional jargon, different standards of ethical behavior, pay scales and work culture, and issues of turf and territorialism (Jehl & Kirst, 1993; Crowson & Boyd, 1993; Waxman, Weist, & Benson, 1999).

LOCATION

Currently, there is no agreement on the most desirable location for integrated health and educational services (Dryfoos, 1994). FSSs can be classified as either school-based or school-linked (Talley & Short, 1995). There exist advantages and disadvantages to each configuration.

The school-based model has all services provided in the school building. The advantage of this model is that services are provided in proximity to students and educators, increasing access to services and facilitating collaboration among professionals. Limitations of this model include limited physical space for added services and the bureaucratic complexities associated with providing medical and social services on school grounds (see Reeder et al., 1997).

The school-linked or community services model provides the services off-campus, typically in a hospital or clinic. The main advantage to this model is greater access to medical and social service providers. Limitations include lack of interaction/integration with educators including teachers and administrators, the expense and inconvenience of traveling for students and their parents, and an emphasis on acute or referral care rather than on prevention (see Reeder et al., 1997). Although, theoretically, there is an expected difference between services offered and location of service delivery, there is little difference in the types of services provided, types of professionals employed, or the role of the school psychologist (see Bucy et al., 1999).

FUNDING

FSSs are typically funded by multiple sources (Reeder et al., 1997; Bucy et al., 1999) including public health funds that originate from the Center for Disease Control (CDC) and are distributed through state public health agencies. Additional funding can be secured through state and federal grants and third-party reimbursement, most commonly Medicaid or MCOs (Armbruster et al., 1999). Funding for prevention activities may be obtained through legislation such as the Anti-Crime Bill of 1994 and the Administration on Children, Youth, and Families, as well as from the Department of Health and Human Services. Private funding sources including private citizens, the Robert Wood Johnson Foundation, and the Hogg Foundation fund a number of FSS projects (DeMers and Bricklin, 1995; Carlson et al., 1996). In some states, private hospitals have established and staffed school-based health clinics.

If school psychologists are to play a significant role in FSSs, and be reimbursed for their services, then they need to negotiate their participation at the time the FSS is conceived (Reeder et al., 1997). They should be at the table when the initial funding is allocated. To be involved early in the development of a FSS, school psychologists should also serve on state level committees, develop networks with health constituencies, and actively pursue funding sources (see Leviton, 1996; Petraitis, Flay, & Miller, 1995).

BEST PRACTICES

Elements of Successful Collaboration.

Effective collaboration with parents, students, community members, and other professionals is integral to the success of the FSS movement. As noted above, difficulties inherent in the collaborative process are responsible for many of the obstacles that practitioners in FSS settings are likely to encounter. Although there is a dearth of scientific evidence about the elements of effective collaboration, a number of thought-provoking scholarly and theoretical discussions on the topic have recently appeared (e.g., Minke, 2000; Sarason & Lorentz, 1998).

Minke (2000) presents a model of collaboration that provides useful guidelines for practitioners struggling with this very challenging aspect of service delivery in the FSS context. The model identifies four "CORE" elements of collaboration, including Connection, Optimism, Respect, and Empowerment. Connection implies the existence of constructive, trusting, and mutually dependent relationships in which conflict is not avoided or minimized but viewed as a strength and used productively. Optimism in considered necessary for sustained effort in the context of this challenging process. It encompasses not only a positive outlook, but also generous assumptions about the intentions and efforts of others, combined with an unwillingness to blame individuals for system-level failures. Respect includes acceptance of difference, willingness to learn from others, and recognition of each collaborator's expertise. Empowerment involves the development of true partnerships among collaborators, including those who may be accustomed to more hierarchical relationships (such as administrators and students). Each participant is assumed to have existing strengths as well as potential for developing new skills.

As they strive to resolve dilemmas and overcome challenges in their new roles, school psychologists working in FSSs are encouraged to consider these CORE elements of collaboration. For example, decisions about how to handle confidentiality and informed consent should be made in consultation with students, parents, and colleagues. Each of these groups should all be represented on advisory boards responsible for setting policies about service delivery. Conflicting opinions may be voiced, but these differences should be embraced rather than avoided. The outcome of a process that thus respects diverse perspectives will likely be superior to one based only on the views of the most powerful stakeholders.

Some barriers to gaining teacher support may be eliminated by providing teacher training that includes team building, understanding service coordination, and training teachers to recognize a fuller array of child mental health problems (Bucy, 1994). Teachers should be included on governance boards. Program evaluation should include academic outcome measures and teacher feedback. Activities that promote a sense of ownership and participation, common planning times, and strong and vocal administrative support from superintendents and principals will encourage teacher involvement.

Problems related to role strain may also be reduced through improved collaboration. Optimistic collaborators in a resource-poor setting would avoid blaming each other for the system's inability to address all students' needs. This attitude might foster a more productive climate in which creative solutions could be developed and implemented. Consistent with the notion that everyone has strengths and can learn new skills, resources may be developed through collaboration with community volunteers and paraprofessionals. Any supervision that is provided should be empowering rather than hierarchical. That is, it should be aimed at increasing the supervisee's competence and not keeping him or her in a subordinate role. Related to this, a collaborative practitioner who believes that new skills can be learned and is willing to learn from others should be comfortable seeking out and accepting supervision to avoid operating outside of his or her areas of competence.

The CORE elements are also integral to collaboration with parents and community members. Trusting relationships must be developed, in which different perspectives are embraced and different types of expertise are acknowledged. Respectful collaboration also implies that before implementing new programs, parents and community members must be consulted to make sure that the proposed services are responsive to the community's needs and consistent with its goals and values.

Training Needs

Continuing education and pre-service training activities may enhance school psychologists' ability to function optimally in FSSs by addressing three broad goals: expand the range of services that school psychologists are trained to provide (including such activities as health education, prevention, and early intervention), expand school psychologists' view of their role to be more consistent with the generalist model, and increase school psychologists' ability to collaborate effectively with other professionals, students, parents, and community members.

Tharinger (1995), argues that the specialties of health psychology, community psychology, clinical psychology, and school psychology are all relevant to the emerging roles for psychologists in the FSS context. Consistent with this, school psychologists may benefit from expanded coursework in these areas. Specifically, some background in health psychology would help prepare school psychologists interested in contributing to health education and behavioral management of medical problems; some background in clinical psychology might be useful for school psychologists interested in providing psychotherapy to students and families in school-based clinics; and some background in community psychology would be relevant to the development of preventive interventions, and would complement school psychologists' knowledge of strategies for consultation and collaboration.

Training experience including practicum and internship settings that involve collaboration with other professionals and with parents and students would help prepare school psychologists to effectively engage in these activities. Coursework that provides information about other professions (such as ethical guidelines) might also be useful. Adelman & Taylor (1999) argue that discipline-specific training is one of the barriers to a more generalist approach to service delivery. Training programs that take an interdisciplinary collaborative team approach are described by Papa, Rector, and Stone (1998). These teams, which include health and education personnel, share common courses related to health issues and primary care of children and join each other in clinical placements in school-based and community health centers. There may be greater employment opportunities for those with broader training.

To take on leadership roles in FSSs, school psychologists, particularly those at the doctoral level, must expand their skills even further. Training or experience in program administration including program planning, budgeting, personnel management, and information systems management will prove necessary to develop and administer FSSs (Illback, 1994). Many of these opportunities are already available to school psychologists who administer pupil personnel or special education services within school districts.

SUMMARY

Today's school recognizes the interrelationship of a child's education and his or her medical and mental health. To be fully effective in the twenty-first century, schools must be able to address the needs of children beyond the 3 R's. FSSs, offering comprehensive, integrated services, address many of the barriers to education that are experienced by children today. School psychologists have much to contribute to full service schools in the areas of prevention, intervention, collaboration, program development and administration, and research. The school psychologist is uniquely trained to provide many of the needed solutions to the challenges accompanying the FSS model.

Best Practices in Promoting Educational Reform at a School District Level

C. Ben Barbour
Horry County Schools, Conway SC

OVERVIEW

Educational change can be viewed as a continuum of implementation ranging from macro to micro. Macro changes at a systems level can come from national and state legislative directives while micro changes at the Local Education Agency or district level are often referred to as new initiatives and/or policy changes. Macro changes tend to be sweeping and all-inclusive. Such changes at the national level would include the Education for all Handicapped Children Act of 1975 (P.L. 94-142) and its progeny the Re-Authorization Act of 1997. An example of macro changes at the state level is Kentucky's Education Reform Act, which adopted new state standards, and South Carolina's Education Accountability Act of 1998, with its emphasis on assessment and standards alignment with measurable results.

While macro changes often are initiated by enactment of laws or in response to broad-front litigation, changes at the district or LEA level (micro) often can be traced to activity initiated at an individual, departmental, or school level. This activity can be viewed as reform from the inside out and tends to encourage current practices becoming more streamlined and responsive to meeting the needs of students. It also offers the opportunity for school psychologists to adopt the role of systems change agents (Knoff, 2000) and problem solvers (Deno, 1995).

What follows is a review of lessons learned from one district's attempt to change from a special education system that places emphasis on issues such as eligibility, specific criteria for placement, and indirect measurement to a system that places emphasis on meeting the needs of the student. While still an ongoing metamorphosis, knowledge gained through the limited implementation of a different model has been put to use immediately within existing structure to benefit all district students.

BASIC CONSIDERATIONS

Historical Context

Why would any LEA want to explore different avenues for implementation of an alternative service delivery model? In the case of this district, two factors led to the recognition that desired outcomes were not being obtained by existing procedures.

The first factor was general dissatisfaction by the special education administrative team with the prereferral process in place at the time. The process in place, known as the Student Assistance Team (SAT), had started years before with the best of intentions. The purpose of SAT was to help teachers develop interventions for student improvement and to act as a process rubric for students deemed in need of referral for special education determination. Unfortunately, the process deteriorated into a rubber stamp for entrance into special education services. It became simply something one "had" to do to get a student evaluated. Internal yearly audit information indicated that increasing numbers of students were being referred through the SAT for psycho-educational evaluation, and only about half were qualifying. This trend represented a questionable allocation of the district's school psychologists' time and produced a dilemma in justifying the continued district use of outside contract testing. Clearly, the process was not accurately predicting or producing appropriate candidates for special education consideration. In addition, the audits indicated that SAT interventions existed more on paper than in practice. By definition an intervention has both a direct instruction and progress monitoring component. Few, if any, of the interventions typically listed through SAT met this criterion. Also, interventions were almost identical for each student going through the process, regardless of the student's presenting problem.

A second factor that came into play was a result of a meeting with Dr. Dan Reschly, of Vanderbilt University, who was presenting to the spring conference of the state association of school psychologists. Reschly spoke on "School Psychology: Demise of the Old Time Religion and the Emergence of a New Paradigm" (Reschly,1998). He proposed a macro shift in traditional practices and thinking. Such practices and ideas include beliefs such as (a) disabilities viewed as being inherent in the individual, (b) the identification and treatment of underlying causes, (c) advocating unique treatment methods by disability, (d) advocating unique teacher training by disability, and (e) assessing aptitude to prescribe treatment. The proposed replacement paradigm called for a shift toward increasing use of functional assessment, a call for non-categorical entitlement with mildly disabled students, initiation of data-based decision making, and increased promotion of research-validated interventions.

These two factors occurring in a similar time frame acted as a catalyst for change. The decision to look at an alternative approach for delivering services to students did not evolve from a "big bang " organizational mandate. Instead, the idea of re-formatting what the district was doing evolved incrementally over a series of informal discussions among various professional staff members.

To help clarify for the district what a functional needs-based problem-solving model would look like, Dr. Reschly was contacted and subsequently came to the district and presented ideas over a 2-day period. Both school psychologists and administration personnel were asked to attend and to participate in a dialogue for further clarification. Individuals from state organizations, and higher educational institutions, other school districts, and the state school psychology association were invited so participation would be representative. Over the subsequent spring months, planning took place regarding the formation of a problem-solving team concept to replace the previous pre-referral team structure. A somewhat tentative and rather ambitious notion of moving toward a non-categorical approach vis-à-vis the identification and placement of special needs students also came under discussion.

The events that occurred from the spring of 1998 to the present are the subject of the rest of this chapter.

Infrastructure

The decision to move toward a non-categorical problem-solving model was based on a firm conviction that the district's students (regular and special education) would be the primary beneficiaries of a system that reversed the sequence that was being practiced. Instead of focusing attention on evaluation and eligibility issues at the front end of the process, why not try to meet the presenting needs of the student first and have entitlement or eligibility issues addressed later as an integral component of the overall model and dependent on the outcome of the earlier problem-solving efforts?

Identified necessary steps toward implementation of a new model included the following:

1. Securing permission from district superintendent

2. Development of new problem-solving team approach with emphasis on early data-based interventions

3. Incorporating a different measurement technology for progress monitoring purposes

4. The development of local norms for standardization purposes

5. Committing to increases in staff development and gaining staff cooperation.

6. Request to the state's Department of Education for permission to enact rules replacements (exceptions)

PERMISSION

The first step was accomplished by meeting with the superintendent, director of special education, and assistant superintendent for learning services. Permission was secured to explore this different model with the understanding that procedural safeguards and due process rights would continue to be honored and protected. This was not a difficult permission to obtain since many of the advantages of working in a problem-solving model coincided with district aims and philosophy. The district's insistence on and commitment to the idea that all students can learn proved useful for obtaining a favorable decision.

STUDENT STUDY TEAM

The second element identified as a critical component was the development of a Student Study Team (SST) based on the problem-solving model. There are numerous variations of problem-solving models referenced in the literature (Ysseldyke & Marsten, 1998). Generally they all have three basic components of (a) formulating or defining the problem, (b) generating and selecting potential solutions, and (c) testing the selected alternatives. The model adopted incorporated facets from such states as Kentucky, Iowa, Ohio, Florida, and Pennsylvania. This study team approach would not be solely a pre-referral approach and would be implemented over a 2-year period to include all K–5 schools in the district. The distinguishing features included the following:

1. A focus on problem-solving, but not as a mechanism for referring students to special education evaluation

2. A focus on modifying the environment to assist students

3. A focus on assessment of what the student knows and can do, and not on weaknesses

4. An assessment that is very functional and diagnostic in nature and can be performed by teachers

5. Interventions that are based on data and research

6. A personalized intervention or learning plan developed using a meaningful intervention connected to data generated from informal assessment

7. A personalized intervention with a monitoring and evaluation component to determine effectiveness

8. Problem solving with basically four levels of involvement
    - Informal parent conferences
    - Informal consultation with additional professionals both in and outside of school
    - Formal consultation with SST and development of intervention plans as needed
    - Consideration for programs such as Special Education or 504 designation.

MEASUREMENT

Measurement for progress monitoring and local norm development was derived from the Basic Skill Builders Program (Beck, Conrad, & Andersson,1995), which incorporates the direct measurement system developed by Dr. Ogden Lindsley and is known as the Precision Teaching model (Lindsley, 1972). The Basic Skill Builders program is a collection of 1-minute probes or Skill Builder Sheets that can be used to assess present academic or behavioral levels of functioning. The measurement guidelines accompanying the program allow for data-based instructional and curricular decision making. When used in conjunction with standards alignment or the development of local norms, the program offers a wealth of information based on direct assessment with a minimum of time invested. This skill building model can be used in conjunction with other instructional approaches "as long as these approaches have some evidence of effectiveness" (Beck et al.,1995.)

LOCAL NORMS

The development of local norms is a critical variable when attempting to shift to a problem-solving model with its emphasis on curriculum-based instruction and curriculum-based measurement. Mark Shinn's (1988) work was a valuable reference vis-à-vis creating and implementing local norms. An out-of-district statistician was contracted to consult for the first set of assessments. It was decided that the assessment team would be composed of 12 individuals, and a demographic study indicated that the best composite sample, based on several different criteria, were four K–5 elementary schools. All classes were general education classes. Three team members were assigned to each school, and the assessment lasted three consecutive days. One class per grade level in each school was assessed by using previously selected 60-second probe sheets in grade-appropriate academic areas.

The number of academic probes per grade ranged from four to eight. The academic probes were aligned with district standards. After 3 days of assessing each of the four schools, the results were collated and tabulated. The results were sent to the statistician. The final results produced a Spring Quarter set of norms that could be used for reference and standardization purposes. Since the initial assessment, Fall and Winter Quarter norms have been added that complete the cycle.

STAFF DEVELOPMENT

The need to commit to extensive staff development was realized early. In the spring and late summer of 1999, two teams representing the district went to Marshalltown, Iowa (Area Education Agency 6). The first trip was for fact-finding, and the team was composed of school psychologists, learning specialists, and special education administration personnel. The purpose was to get more information about creating and implementing a non-categorical problem-solving model. Iowa has had this type of model in place and working for almost a decade, so Iowa was a logical place to start the learning process. The training was composed of presentations by various Area Education Agency 6 staff members regarding history and evolution over the decade. District representatives were given ample opportunity to ask questions and discuss projected problems or obstacles.

The second trip to Area Education Agency 6 was in late July 1999. A team composed of school psychologists and one special education administrator was allowed to participate in a 5-day training session offered for new personnel and others connected to the area education agency. Training centered on performance monitoring in the problem-solving approach. Daily activities stressed such items as problem identification, data review, collaborative consultation, measurement strategy, current levels of performance, discrepancy determination, problem analysis, goal statements, intervention strategies, goal monitoring graphs, implementation components, intervention plan options, and entitlement.

The training and practices learned in Iowa were incorporated into the district's procedure manual for implementation. The new skills learned in Area Education Agency 6 were interwoven with the basic district components already underway: the SST, use of a new measurement system, new skills in curriculum-based instruction, and the development and use of local norms.

Additional skills needed when working with a functional approach were deemed necessary. Dr Ken Howell of Oregon was invited to present a workshop on curriculum-based instruction. When incorporated with the growing database of options under a problem-solving model, such as the SST, the district felt confident about its ability to provide additional quality services to students.

Some personnel reorganization was necessary to ensure that the district would be able to monitor the transition to the SST as well as lead the staff development for implementation of the non-categorical project. A school psychologist was asked to head staff development for the SST, in particular, and the other special projects in general.

Request for Rules Exceptions (Replacements)

In late spring of 1999, the district sent a written proposal to the state's Department of Education requesting three exceptions from the current state special education regulations be granted. States are required to report to the federal government the numbers of individuals served by category. However, from a federal point of view, it is not required that an individual child be labeled with a specific disability for that child to receive special education services. The federal government permits other ways of meeting the state reporting requirement. The federal government has been permissive in the ways that states have been allowed to meet the breadth of the mandate. As Tom Hehir, past director of OSEP, stated in a policy letter (Hehir, 1995):

> Part B does not require States to label children. The definitions of "children with disabilities" at 34CFR300.7 must be used by States to prepare annual data reports for the U.S. Department of Education regarding the number of children in the state receiving "special education" and "related services" under the Part B program requirements. The Department has no objection to a State's use of categories, which differ from those specified in Part B, or, if it elects, the use of a non-categorical approach so long as those children eligible under Part B are appropriately identified and served.

Congress codified OSEP's long-held position on labels with the passage of Individuals With Disabilities Act 1997. The critical passage from the statute reads:

> Nothing in this act requires that children be classified by their disability so long as each child who has a disability listed in section 603 and who, by reason of that disability, needs special education and related services is regarded as a child with a disability(IDEA 97 612(a)(3)(b)).

By using the above information as a springboard, the district asked for three rule replacements to the state special education regulations then in effect. First, in the area of evaluation, the district asked for a rule exception of the comprehensive evaluation requirements as they related to the definition of Learning Disabled (LD) and Educably Mentally Disabled (EMD) within the current state guidelines in order to reflect the proposed problem-solving assessment. The classifications of LD and EMD combined accounted for approximately 68% of the district's mildly disabled special population. The specific request related to intellectual testing and standardized testing instruments. The district proposed to replace this method with a comprehensive problem-solving model of practice. Instead of outlining specific tests or procedures that must be completed in every case, a general structure of data collection to be applied in every case would be delineated. Second, in the area of identification, the district requested that non-labeling of mildly disabled students (LD and EMD) be allowed. The request would allow the district to "entitle" students who have a mild disability and who are not in need of an alternative curriculum without labeling. While a disability label would not be used, the district would identify the characteristics of the student, needs of the student, intervention strategies to be used, the procedures to be used to monitor the success of the intervention, and the level of parental involvement. Such students would be considered as "entitled" to special education services.

The last rule exception dealt with the area of delivery of services (teacher/pupil ratio). The district requested the ability to eliminate current maximum class size for resource and eliminate the requirement of minimal average of resource time per day and replace with amount of time determined by individual child instructional needs (minimum 250 minutes per week). The district would replace the existing requirements with new caseload controls based on the educational needs of students rather than on actual head counts of students. Also, the amount of time would be determined by the individual child's instructional needs (no more than 66 contact hours per teacher).

The information was submitted to the state's Department of Education, Office of Exceptional Children, in May 1999. In essence, the district was asking for permission to pilot three K–5 schools using the problem-solving model with the non-categorical provisions. The district offered to have outside contract testing performed with a traditional psychoeducational battery for parity purposes. For every student in the pilot schools who met entitlement criteria, the district would also have the same student evaluated independently for quality assurance purposes and in keeping with the experimental nature of the project. The response came in late September 1999. While generally positive about the district's willingness to search for innovative approaches to meeting students' needs, the response in effect asked for further clarification and additional input.

Within 2 months a request was made again to the state's Department of Education asking for a meeting to permit district personnel to present the proposal in person. A date was mutually agreed upon for mid December 1999. Chosen individuals from the district made a short presentation and responded to questions. A promise was made that the district would get a response in January 2000.

A response dated January 7, 2000, arrived at the district and gave a carefully worded consent to the district's proposal for establishing three pilot schools for a non-categorical problem-solving approach to meet students' needs. While filled with many conditional statements, their response did offer to allocate grant funds to defray outside contract testing expenses to the district. A probation period of 6 months with written progress monitoring reports was mandated along with insistence on safeguarding the due process rights and guarantee of FAPE as outlined in the IDEA. There would be appointed a linkage or monitoring person/agency to ensure safeguard compliance and facilitate communication. The first annual visit and presentation of site data was scheduled for spring 2001.

Two of the district's school psychologists who had received the Iowa training from Area Education Agency 6 were chosen to lead the SSTs in the three pilot schools. One would lead the SST teams in two of the schools while the other school psychologist would take the other SST leadership role. The respective faculties had been inserviced since the beginning of the school year and were familiar with the different features of a non-categorical model. Implementation began in the three pilot schools during the month of February 2000.

THE ROLE AND FUNCTION OF SCHOOL PSYCHOLOGISTS

Although the pilot implementation has not been operating very long, there have been some measurable changes in the way the two pilot school psychologists distribute their time during the day (see Table 1).

Table 1 indicates that these school psychologists spend significantly more time leading general education teams in problem solving and significantly less time in administering traditional psychoeducational evaluations. One of the interesting aspects of going to the SST concept has been the 50% decrease in referrals for "special education testing." Of the SST referrals that are forwarded on for special education evaluation, 80% are qualifying. This would indicate that the referrals through SST are of higher quality relative to the predecessor SAT, with a better chance for eligibility consideration. Another interesting feature seen in Table 1 is the time spent in direct observation and development of behavior and academic intervention plans. Direct consultation with teachers and parents is noticeably higher in terms of time invested.

By the spring of 2001, there will have been over a year of data collection that it is hoped will show the efficacy of using a non-categorical problem-solving approach to meeting students' needs. Teacher, administration, and parent surveys will be administered to assess what works and where the district needs to improve. Questionnaires assessing role and function satisfaction of the two school psychologists involved in the pilot project will be administered twice during the 2000–2001 school year.

BEST PRACTICES

In retrospect, the largest pitfall was produced by a lack of clear communication during the early period (spring of 1998) when the model was being explored and discussed. This violated the admonition given by Jeff Grimes and David Tilly to "communicate, communicate, communicate!" when implementing educational change (Grimes & Tilly, 1996). The result of not communicating the district's intentions led to the need for

Table 1. **Comparison of how a school psychologist's time was spent during a "typical" month under the rule replacements pilot program versus the traditional school psychology model**

Activity	*Time spent under the rule replacements pilot program, minutes*	*Time spent in traditional model, minutes*
SST meetings	1215	345
Individualized Education Plan meetings	105	210
Special education staffings	1065	1860
Re-evaluation review meetings	120	285
Consultation with teachers	900	615
Consultation with parents	420	255
Consultation with administrators	105	540
Consultation with counselors	none	90
Direct observations	675	75
Indirect observations	180	none
Administering precision teaching probes	1320	195
Traditional psychological evaluations	120	1950
Developing and implementing behavior intervention plans	255	45
Developing and implementing academic intervention plans	75	none

several "call" meetings to straighten out the misunderstandings and relieve some anxiety about jobs and role/function fears. The school psychologists as a group were most affected, and the district had not clearly articulated its intentions regarding how this new model might actually affect them. After a series of meetings, the district could more clearly convey the idea that, if approved, the project would have pilot/experimental status and would only involve two of the school psychologists who had received out-of-state training. There would be no sudden reversal of roles for anyone, and there would be no reduction in the number of school psychologists. While group anxiety is now abated, better communication from the district in the formative stages would have prevented misperceptions and created a more positive atmosphere.

SUMMARY

Throughout this chapter, an attempt has been made to trace the reform efforts of one district. While these efforts may be characterized as ongoing and as a work in progress, the attempt at a paradigm shift in how special education services are delivered at the district and school level has been revealing, particularly as it relates to role and function of school psychologists. The call to move beyond basic gate keeping activities can be traced back several decades. In recent years, articles have appeared showcasing the school psychologist as a "problem solver" and a "change agent." Innovative practices include taking a leadership role in crisis management teams, working via indirect service applications to affect more students more effectively, encouraging more research activities at the individual practitioner level, and emphasizing preventative measures in dealing with discipline issues at a school and district level.

The opportunity to move beyond a strict psychometric role appears to be on the rise across the country. Nevertheless, it is ultimately the individual practitioner's decision as to how best to redefine traditional activities and accommodate an augmented role—if at all. In transitioning to a problem-solving model over the past 3 years, the change in activity for the school psychologists associated with the rules replacement pilot project has been quite publicly noticeable. As outlined in Table 1, there has been a definite time re-allocation as the pilot school psychologists move to more consultative and indirect applications of service delivery. Additionally, these school psychologists have more opportunity for enhancing a leadership role since they are observed engaged in assessment activities in the classroom itself. The numerous consultations with both teaching staff and administration tend to promote a new perception of how school psychologists utilize learning theory applications to benefit students as well as to provide ongoing staff development to both regular and special education teachers.

The decision to transition to a problem-solving model at a district level was based on several beliefs, some of which have been articulated previously (Tilly, Reschly, & Grimes, 1998) and can be encapsulated as follows:

1. Use of the problem-solving model in special education service delivery delivers effective data-based assessment and decision-making in an efficient manner.

2. All students can learn and be educationally successful.

3. The primary purpose of problem solving is to solve problems by designing effective individual interventions.

4. Problems affecting student performance do not exist exclusively within the makeup of learners but occur as the result of an interaction between learner characteristics and the educational setting.

5. The effectiveness of a solution cannot be determined prior to implementation. Therefore, solutions must be implemented, monitored, reviewed, and changed as necessary.

6. Problem-solving procedures are best applied as part of a school-wide effort.

7. A problem is not defined as the difference between a learner's potential and achievement but as the discrepancy between the demands of the educational setting and the learner's performance in the setting.

8. Owing to the nature of the problem-solving model, alignment with district/state standards and initiatives is comparatively simple and aids in documenting accountability.

On the basis of their training, school psychologists have a wonderful opportunity to assert a strong leadership position within a problem-solving approach. If "best practice" can be defined as doing what is right for the child, then it seems reasonable that a district can focus its collective experience, collective intelligence, and collective beliefs to improve the educational prospects for all students.

AUTHOR NOTES

I am pleased to acknowledge the contributions and continuing efforts of the school psychologists and administrative visionaries who believe positive systemic educational reform can occur if we remain steadfast to the goal of improving the futures of all students. The following school psychologists are recognized for their integral support and dedication to this project: Tom Jenkins, Tom South, and Te'Anne Cahill. Thanks are extended for the administrative guidance and building-level support of Dr. Gerrita Postlewait, Dr. Brenda Tanner, Mollie Laut, John Robinson, Leon Hayes, David Powell, and David James. A special thank you goes to Dr. Sam Broughton of Francis Marion University for his literature review and editorial assistance. Thanks also to Meg Torrens for her technological assistance.

Best Practices for School Psychologists in Educational Accountability: High Stakes Testing and Educational Reform

Jeffery P. Braden
University of Wisconsin—Madison

OVERVIEW

Educational accountability, high stakes testing, and educational reform are major concerns for U.S. schools. School psychologists can help schools respond to accountability mandates, high stakes testing, and educational reforms. This chapter is designed to empower school psychologists to partner in schools' efforts toward accountability and educational reform by reviewing the educational accountability and reform movement, the stakes associated with assessments, students with disabilities in accountability programs, and specific activities school psychologists may consider to help schools with accountability, high stakes testing, and reform.

THE EDUCATIONAL ACCOUNTABILITY AND REFORM MOVEMENT

The educational accountability movement is an historical reaction to growing public concern about the success of U.S. schools. Publication of *A Nation at Risk* (National Commission on Excellence in Education, 1983) nearly a quarter century ago spurred a movement toward public accountability for schools. The public accountability movement shifted public emphasis from interests in equal educational opportunities (e.g., the 1960s War on Poverty) to emphasis on educational outcomes (Ravitch, 1999). The 1988 Education Summit, called by President George Bush and chaired by then-Governor Bill Clinton, led to the development of national educational goals (e.g., National Education Goals Panel, 1995) defined in part in terms of student performance on educational tests. Both political parties also adopted platforms opposing "social promotion," or the promotion of students to higher grades based on age rather than demonstrated academic accomplishment.

As a consequence of pressure to improve student outcomes, federal education funding entitlements added requirements that states adopt challenging educational standards and provide evidence that schools within the state were continuously improving student performance. The Elementary and Secondary Education Act (ESEA) and the Improving America's Schools Act (IASA) require that states adopt standards for what students should know and do, and have some mechanism for monitoring students' progress toward those standards. As a consequence, all 50 states have adopted educational standards and a standardized approach for measuring student learning. The most common form of these standardized measures is the group-administered standardized achievement test (*Education Week*, 2001). These tests are typically administered in elementary school (third or fourth grade), middle or junior high school (eighth grade), and high school (ninth or tenth grade).

Standards-Based Educational Reform

Educational accountability requires that the public establish the outcomes desired from schools, and then measure progress toward those outcomes. The logic of standards-based educational reform is that, by publicly and clearly communicating to educators, students, parents, and the public what students are to know and do, and by measuring how well students meet these goals, success can be recognized—and low performing schools will be encouraged to change (reform) their educational practices to improve student outcomes. Thus, standards and assessment are at the heart of the educational reform movement (Ravitch, 1999; Thomas B. Fordham Foundation, 1998).

There are two major types of standards: student standards and opportunity to learn standards. Student standards establish what students should know and do. There are three types of student standards:

1. *Content standards* are typically subject matter specific (e.g., language arts, mathematics), but are broadly stated so that they define performance that spans a large range of complexity and levels of performance.

2. *Performance standards* are more specific than content standards, and linked to specific grade levels. These standards attempt to describe what students should know and do at various points (e.g., fourth, eighth, and twelfth grades).

3. *Proficiency standards* state how well students must perform to be judged proficient, or meeting the standard. Proficiency standards may be defined by cut scores on tests, rubrics for judging student work, or other operational definitions of student performance.

Each of these forms of standards is complementary. Content standards establish what students should know, performance standards establish what students should do, and proficiency standards establish how well students must do to be judged as meeting the standard. In many states, performance and proficiency standards are used interchangeably, creating two forms of student standards: content and performance (Cizek, 1998). Also, some states use "benchmarks" instead of "performance standards" to define the criteria by which educational stakeholders should define student success.

Opportunity to learn standards (OTL) establishes the supports students need to acquire high levels of academic proficiency. OTL standards are intended to hold educators, schools, districts, administrators, and the public accountable for providing children the opportunity to acquire challenging academic competencies. Unlike student performance standards, federal law does not require states to monitor and enforce OTL standards; they are optional (Porter, 1995). Thus, states are required to establish and to show continuous improvement on student performance measures, but states are not required to establish and enforce OTL standards. OTL standards have, to date, played a much less direct role in encouraging educational reforms, despite efforts to clearly define what the public should expect from all educational stakeholders (Education Commission of the States, 1998). Instead, the focus of standards-based educational reforms and accountability falls primarily on measures of student performance (*Education Week*, 2001).

Measures of Student Performance and Educational Accountability

There are many measures of students' academic proficiency. Most measures are standardized (so that testing conditions and educational demands are common across all settings and districts), fairly brief (so that they do not take much time), and aligned to state standards (so that they are credible indicators of proficiency in the standards) (Cizek, 1998). Unfortunately, various aspects of educational accountability systems are confused, and terms are often used inappropriately (see the resources in Appendix A for glossaries and primers on assessment of student achievement). Therefore, it is useful to separate the measures educators use to assess student performance, the methods used to analyze data from those measures, and the consequences attached to the results of the measures.

MEASURES OF STUDENT PERFORMANCE

Standardized, selected-response tests are the most common method for measuring student performance in educational accountability systems. Several states supplement standardized tests with essays, but only seven do so for subjects other than language arts (*Education Week*, 2001). Two states use portfolios (Kentucky and Vermont), and some others include on-demand performance assessments, standardized teacher ratings, and other forms of educational assessment. However, all states use assessments (whether selected- or constructed-response) that are standardized, so that methods for collecting, evaluating, and reporting student performance data are constant across students, schools, and districts (*Education Week*, 2001).

It is important to be precise in using terms related to assessment. For example, many educators believe the phrase "norm-referenced test" describes an assessment consisting solely of multiple-choice questions whose item content is determined solely by normative item characteristics, rather than academic standards or content. This is unfortunate, not least because it is the score—not the test—that is referenced to a norm (see next section). Also, the three major standardized achievement tests (i.e., the Iowa Tests of Basic Skills, the Stanford Achievement Test-Ninth Edition, and the TerraNova) use item content aligned to national or state standards, and include short-answer and brief essay items or prompts (Cizek, 1998). Furthermore, these standardized achievement tests are designed to measure skills and reasoning, rather than just knowledge. For example, a social studies test is more likely to provide a map, and then ask questions such as, "What is the most populous city shown on the map?" or "Which city is most likely to be a hub for imports and exports?" than to ask questions such as, "What is the capital of Sri Lanka?" or "In what year did the U.S. Civil War begin?" Likewise, reading tests use multi-paragraph passages of original literature as a source for questions. Unfortunately, many educators are unaware of these test features, because they often presume "norm-referenced tests" are composed exclusively of multiple-choice items that demand recognition and regurgitation of arbitrary information.

REPORTING OUTCOMES OF LARGE-SCALE ASSESSMENTS

The results of accountability measures are most often reported in criterion-referenced or standards-referenced scales (Cizek, 1998). That is, rather than reporting student performance relative to a norm (e.g., percentiles, normal curve equivalents), most states describe student performance relative to proficiency standards. Consequently, student performance is typically described in four to five categories relative to proficiency standards. For example, Florida defines student performance with five levels (i.e., little success, limited success, partial success, success, and success with the most challenging standards), and describes student scores with four categories (i.e., Minimal Performance, Basic, Proficient, or Advanced). Most states define proficiency levels by developmental scale scores, which are based on item response theory. Developmental scale scores form an equal interval scale, with an (estimated) true zero point. These form a scale that allows for measurement against an absolute standard. Scores from different test levels can be placed against this common standard.

School psychologists should not confuse developmental scale scores with the scaled scores produced by most psychoeducational tests. Whereas scaled scores are arbitrarily fixed to the mean of a distribution, developmental scale scores are fixed to an estimated "true" zero point. Scaled scores are similar to Fahrenheit and Celsius scales, which fix zero to an arbitrary point, whereas developmental scale scores are like the Kelvin scale, which fix zero to a point estimated to be "true" or absolute. This allows tests to report how students are doing across different versions of a test in the same scale (e.g., a developmental scale score of "645" reflects the same estimate of competence whether it is earned on a third grade or sixth grade version of a test). For this reason, most states define proficiency levels by developmental scale scores, not norm-referenced scores. Achievement tests also produce norm-referenced scaled scores, called "normal curve equivalents" (NCEs). NCEs are fixed to a mean (50) and defined by a standard deviation (21.06); the odd value for the standard deviation is selected so that NCEs of 1, 50, and 99 match percentiles of 1, 50, and 99.

Although large-scale tests can report student scores in norm-referenced terms (e.g., NCEs, percentiles), they can also report student scores in criterion-referenced terms (e.g., scale scores, proficiency levels). For this reason, avoid the term "norm referenced test" to describe standardized achievement tests. It is the score, not the test, that is referenced to a norm (or criterion). Just as the number of pushups a person does can be described with respect to norms (more or less than average) or a criterion (meets, does not meet, exceeds the standard), likewise the performance of a student on a test can be described with respect to norms or criteria. The test (e.g., pushups) is neither norm nor criterion referenced; rather, it is the score or performance that is linked to norms or criteria. The distinction between tests and results being described relative to norms or criteria is important, because criterion-referenced descriptions of performance allow states to measure progress regardless of normative changes. For example, if the average level of student achievement dropped steadily over a decade, half of the nation's students would still be above the mean. Conversely, if the average level of student achievement improved, half of the nation's students would still be below the mean. For this reason, most states have eschewed norm-referenced scores (e.g., grade equivalents, national percentiles) in favor of proficiency standards that are linked to a zero point fixed independent of the national mean.

How do states decide where to set proficiency standards? Most states set proficiency standards using a bookmarking procedure. (See Appendix A for an on-line example of bookmarking.) In this procedure, groups of people with content and grade-level expertise (usually subject matter teachers recruited throughout the state) review the entire bank of possible test items across all testing levels (e.g., K–12 grade forms of the test). The easiest test item in the bank (e.g., the easiest question on the kindergarten version) is printed as the first page of the book, and items are ordered so that the most difficult item is the last page of the item book. The experts use bookmarks (literally) to mark the point where they believe item difficult moves from a lower level of proficiency (e.g., emerging or minimal performance) to the next highest level of proficiency (e.g., basic or developing). The idea is that students who can pass items "above" the bookmark have a higher level of proficiency than those who are only able to pass items below the bookmark. Then the panel members discuss where they placed the bookmarks, and discussion continues until they reach consensus. Some states inform the panel what would happen if they adopted the bookmarks by applying proposed cut scores to test data and describing the proportion of students falling into each proficiency category. When the process concludes, the state uses the developmental scale scores corresponding to the bookmarks to define proficiency.

Educators should realize three things about this process. First, experienced, grade-level teachers (e.g., not statisticians, politicians, or other non-educators) set proficiency standards. Second, proficiency standards may vary across subject matter and across states as a consequence of this procedure. For example, mathematics teachers tend to set higher cut scores than social studies teachers, and teachers in some states may set higher standards than those in other states. Finally, standards are not linked to norms; they are linked to subject-matter criteria.

STAKES OR ASSESSMENT CONSEQUENCES

Sanctions and Rewards

Although the phrase "High Stakes Test" is popular (and even appears in the title of this chapter!), it is important to appreciate the test itself has relatively few consequences for individuals. For example, TerraNova or Iowa Test of Basic Skills scores have no particular consequences until educators and educational systems attach consequences to those scores. Consequences fall along a continuum, from low stakes (having relatively few/minor consequences) to high stakes (having many/significant consequences) (see Heubert & Hauser, 1998).

1. Low stakes. Consequences are not directly tied to individuals involved in the assessment (students, teachers). Examples include collecting and reporting school or district results with no formal sanctions or rewards.

2. Medium stakes. Consequences are indirectly tied to assessment stakeholders, but the effects are delayed or nonspecific. Examples include the allocation of additional resources or loss of autonomy associated with test scores reported for schools or districts.

3. High stakes. Consequences are directly attached to individual stakeholders (students, teachers), and have major significance for their lives. Examples include promotion, retention, and graduation for students, and performance pay, personnel evaluation, and continued employment for teachers.

The higher the stakes, the higher the standards for the assessments used to make these decisions. A test may be valid for low or medium stakes uses, but not for high stakes decisions. The standards tests should meet for these uses are detailed in professional standards (see American Education Research Association

[AERA], 2000; AERA, American Psychological Association [APA], National Council on Measurement in Education, 1999; APA, 2001, for more information). These standards uniformly argue against making decisions on a single test score, and note that opportunity to learn is a necessary precondition for effective use of any test score to reflect student achievement. Some of the key consistencies among these standards, and other work (e.g., Heubert & Hauser, 1998), appear in Table 1.

Sanctions and rewards vary considerably across districts and states (Linn, 2001), but the majority use student performance data to make decisions about school success (*Education Week*, 2001). For example, in Vermont, school data are reported to the public, and there are few other direct consequences for any educational stakeholders. In contrast, Florida policy uses test data to make individual student decisions (promotion, retention, and graduation), provide sanctions (e.g., loss of autonomy) to low-performing schools, give rewards ($300/student, to be used as the school deems fit) to high-performing schools, and provide private school vouchers to parents of children enrolled in schools that are low performing two consecutive years. Chicago Public Schools has its own system, in which test scores are the exclusive criterion for judging school adequacy. Schools that consistently and dramatically fail to meet expectations are reconstituted (i.e., all school employees are released from positions at that site). The local school council for the site will then hire a new staff, some of which may have worked at the site prior to reconstitution; staff not rehired may look for other positions within the district. Other districts and states are experimenting with performance pay (linking teacher salaries and bonuses to test scores), automatic admission or scholarships to state universities (for high student scores), and other incentives and consequences.

It is important to note that, although the specifics of accountability systems vary, they share some common principles:

1. Low scoring schools lose autonomy, not funds. Most accountability systems either maintain or increase funds for low scoring schools, but also provide technical assistance (which is often involuntary) or simply replace administrators.

Table 1. Guidelines for high stakes testing

- *Provide opportunity to learn.* Although agencies may hold students, teachers, and others accountable for student progress, it is unreasonable to hold students accountable for success unless they have been provided with the opportunity to learn the standards.
- *Never use a single score for decision making.* Making high stakes decisions on the basis of a single score is unwarranted in part because of the error in any test score, and in part because emphasis on a single score will inevitably distort the educational enterprise.
- *Provide multiple opportunities.* Students should be given more than one chance to demonstrate proficiency, and, therefore, should have multiple opportunities to take a high stakes exam. Likewise, examinees who fail an exam should be provided with the opportunity to learn exam content prior to retesting so that they can be successful.
- *Use multiple sources of information to make decisions.* Rather than rely on a single test score, high stakes decisions should include other forms of evidence, including information from the classroom, other tests, portfolios, or other evidence of student competence.
- *Assess unintended, as well as intended, consequences.* High stakes attached to test scores are intended to have beneficial effects on student learning, but accountability systems must identify and respond to unintended consequences, such as curricular narrowing, selection of inappropriate teaching strategies, or loss of opportunity to learn.
- *Align tests to standards and validate them for each use.* It is reasonable to hold students (and others) accountable for student learning only if high stakes tests are accurately aligned to standards. Likewise, tests developed and validated for one purpose (e.g., school or district accountability) must be validated for other uses (e.g., student graduation or promotion).
- *Provide clear rules for inclusion and accommodation.* Who takes the test, and under what conditions, is essential for fairness and accountability in high stakes testing. Students with disabilities, and those whose primary language is not English, may require accommodations or other supports to yield a valid and reliable assessment.

Sources for this table include AERA, 2000; AERA, APA, NCME, 1999; and APA, 2001.

2. High scoring schools gain praise, autonomy, and (sometimes) funds. Twenty states provide direct fiscal incentives for high test scores, but nearly all systems include publicity, praise, and increased freedoms (often in the form of decreased external scrutiny) to high scoring schools (*Education Week*, 2001).

3. Schools are always a unit of analysis. Although consequences may or may not accrue to individual students, teachers, classrooms, and districts, all states have some method to identify and intervene with low scoring schools. This is largely inspired by federal legislation, which requires states to have some mechanism to identify schools in need of improvement, and to take steps to improve such schools. It is important to note that federal law does not require any specific sanctions, nor does it require consequences for students, teachers, or other stakeholders.

4. There are more individual consequences for students than for adults. Although 23 state legislatures have passed legislation requiring the use of test scores for promotion, graduation, or both (National Governors Association, 1998), only six states offer incentives (e.g., scholarships) to students, and only three states have passed any specific consequences for teachers, administrators, parents, or other adult stakeholders based on student test scores (*Education Week*, 2001).

Intended Outcomes

Educational systems attach stakes to assessment results to achieve various goals. A fundamental premise behind the educational accountability movement is that the education could be better. That is, careful monitoring (and, in higher stakes systems, sanctions and rewards) will induce educators, students, and parents to be more effective in promoting student learning. Thus, assignment of rewards and sanctions based on test results is merely a means to increase the intended outcomes of accountability. The intended outcomes of educational accountability programs include:

1. Curricular alignment. In some settings, state standards, classroom instruction, and tests are not aligned. That is, what the state intends for students to know and do, what teachers teach, and what tests test are three different things. Assuming that states have aligned their assessment systems with their standards (an issue discussed later in this chapter), assessment results indicating low levels of performance should prompt self-examination and consideration of how best to align instruction and curricular materials to state standards.

2. General efficiency increases. Poor outcomes should invite consideration of resource allocation, particularly with respect to non-classroom expenditures (e.g., administration, transportation).

3. Increased motivation. Consequences for students and teachers are intended to increase the effort toward educational achievement. Although many may take offense at the presumption that they are not already trying their best, many individuals outside education (and even some within education) suspect that some individuals are not motivated to teach or to learn.

4. Educational equity. Disaggregating test results by student groups (e.g., ethnicity, gender, socioeconomic or disability status) should inspire educators to carefully examine the degree of educational equity they provide to historically underserved (and low-performing) groups. Simply reporting the mean of all scores may lead to inaccurate conclusions about the relative success or failure of schooling for a particular group.

The logic and popularity favoring accountability as a mechanism for school reform exceeds the evidence. That is, although test scores tend to improve when accountability programs are put into place, the gains are not large, tend to level off after a few years, and do not generalize to other tests (Linn, 2000). Also, the validity argument to support the use of large-scale tests as a mechanism for improving education is missing two key forms of evidence (Haertel, 1999): (a) that test scores reflect skills that generalize to other contexts (e.g., to what degree do tests reflect skills needed for post-school success?), and (b) that school test scores reflect quality of schooling (rather than other factors, such as student demographics).

The latter issue will be addressed later in the section on methods of accountability. Despite the incomplete evidential base, legislative and political support is strong for mandated accountability, and will remain so for the foreseeable future.

Unintended Outcomes

Although the intended outcomes of educational accountability systems are laudable and popular among educators and others, the unintended consequences of accountability systems may undermine the achievement of intended outcomes (see Coffman, 1993, for a discussion). Unintended outcomes of educational accountability programs include:

1. *Curricular narrowing.* Known in its most extreme form as "teaching to the test," curricular narrowing describes educators' restricting the range and depth of academic content coverage to those topics and responses they think will be on the test. Curricular narrowing can range from broad efforts (e.g., reducing or eliminating music, arts, or athletics) to narrow efforts (e.g., giving practice tests, emphasizing multiple choice items on classroom assessments). Curricular narrowing is also found in teachers' tendency to shift from constructivist, thematic, and "deep" forms of student learning and pedagogy (see Braden, Schroeder, & Buckley, 2001) to superficial coverage of a wide range of topics (sometimes termed the "spray and pray" method of instruction).

2. *Scholastic demoralization.* This phenomenon occurs when students (and to a lesser degree, teachers and parents) are repeatedly confronted with evidence of poor progress and competency. Consequently, many students move from overt frustration to resignation, as evidenced by reduced classroom involvement, infrequent completion of homework, and poor attendance, truancy, and drop out. Although this phenomenon may be precipitated by poor performance on any form of achievement assessment (e.g., teacher tests, quizzes, homework), and its most commonly cited source is low grades (not tests per se), regular, formal assessment may contribute to scholastic demoralization among low scoring students (WestEd, 2000).

3. *Corruption.* Efforts that individuals take to increase test scores that invalidate those scores are efforts to corrupt the accountability system. Examples include student cheating (bringing in answers or other resources not allowed in the test), teacher cheating (giving advance copies of the test, test answers, or other supports not allowed before, during, or after the test setting), and administrator corruption (changing test answers, encouraging test practices that are forbidden). Although most corruption efforts aim to inflate test scores, some accountability systems may be corrupted by deflated or inappropriately low test scores. For example, states are required to show that schools meet standards; establishing low standards would result in high rates of success, but would corrupt the accountability system.

4. *Inequitable educational opportunity.* Students who are at-risk of low scores, or who have achieved low scores, may be assigned to different classrooms than higher performing peers. This form of tracking may lead to different, and generally less desirable, educational opportunities. Conversely, schools may allocate teachers, materials, and other resources disproportionately to low scoring or at-risk students, or grades in which testing occurs, thus denying appropriate educational opportunities to other students. Likewise, teachers may avoid seeking positions in schools with low scores, and in grades where testing occurs (Darling-Hammond, 2000). This leads to less experienced and less qualified teachers working in schools most in need of quality instructors, thus reducing OTL for children in those schools and grades.

5. *Panic.* Accountability programs have been remarkably successful at gaining teacher and student attention through the use of medium or high stakes consequences. Unfortunately, some programs may be too successful! Extreme levels of anxiety and arousal inhibit thoughtful, determined, and complex responses—and are likely to encourage some of the unintended consequences described above (e.g., curricular narrowing, corruption, tracking) (see Lerner & Tetlock, 1999, for a discussion of psychological factors in accountability).

These unintended consequences are not inevitable outcomes of educational accountability systems. Rather, they are most likely to occur when educators, students, and parents lack effective methods, appropriate supports, and personal control over learning and teaching. Unintended consequences can be mitigated or prevented by helping students, teachers, and parents meeting these needs (as discussed at the end of this chapter). Furthermore, there is little direct evidence to show that these consequences are prevalent or substantially undermine the intended consequences. If the case supporting accountability testing is incomplete, the case against it may be less complete.

Methods of Accountability

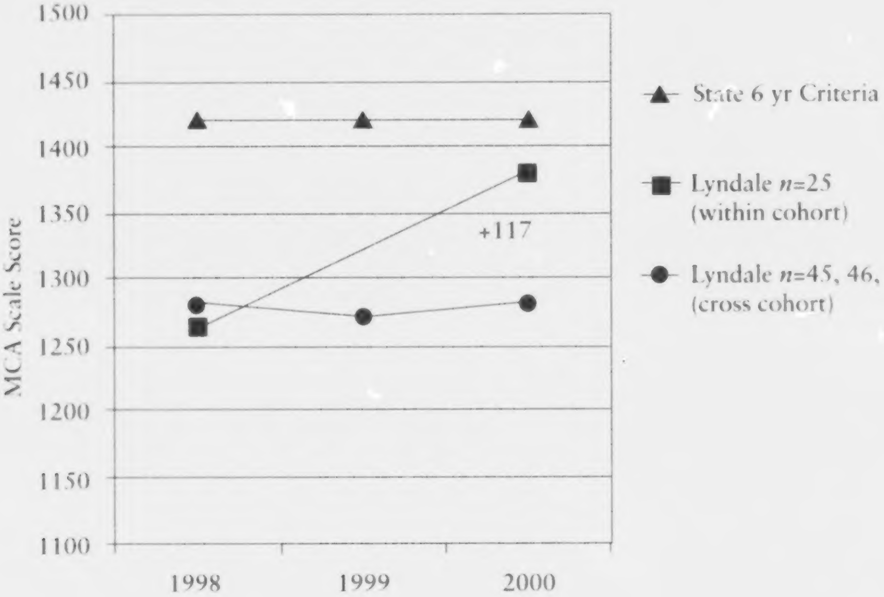
There are three methods for using assessment results to hold schools accountable (Linn, 2001). The first method, known as "current status," simply reports data from a given group in a given year, and compares that report to a standard. The second method compares data from the same group (e.g., students in fourth grade to the same students in fifth grade) to determine whether a school is making adequate yearly progress. This method is called the longitudinal approach by Linn (2001), and the value-added method by Meyer (1996), because it examines how much a student has progressed (or how much "value" a school has added) in a year. The third method is the quasi-longitudinal approach, in that it examines changes over time, but does not necessarily include the same cohort of students. For example, states may use two different groups (e.g., fourth graders last year to fourth graders this year) to determine whether a school is making adequate yearly progress, or all the students in a given grade over successive years (e.g., the fourth grade in 2001 to the fifth grade in 2002).

Each of these methods has its benefits and drawbacks. The current status method is inexpensive and easy to capture (it requires testing only at a fixed grade every year), and easy to calculate and understand (simple means). However, the current status method confounds student population with educational practices. That is, test scores generally have more to do with student populations than with instructional practices (Linn, 2001; Meyer, 1996). This is a fundamental challenge for accountability programs (Haertel, 1999). Longitudinal or value-added methods are more expensive (they require the same children to be tested at least annually) and more difficult to capture (student mobility is a challenge) and calculate (one must link data student-by-student across test episodes). However, value-added methods allow decision makers to assess the impact of educational experiences independent of student characteristics (e.g., each student serves as his or her own baseline), and allow decision makers to disaggregate data by ability range (e.g., are gains for the lowest, middle, and top 10% of students comparable?). Longitudinal methods provide some of the benefits (relative simplicity of reporting, ease of capture) and drawbacks (ignores mobility, only reports group averages rather than within-student change) of these systems. Quasi-longitudinal methods share some of the benefits, and drawbacks, of each of the other approaches.

Figure 1 provides an example of how current status, quasi-longitudinal, and longitudinal models might lead to different conclusions about school effectiveness. This example is drawn from Minneapolis Public School's accountability program (Spicuzza & Heistad, 2001). The school in this example (Lyndale) is an urban school with a high minority, low socio-economic student body. The ordinate shows the mean Minnesota Comprehensive Assessment (MCA) scale score. Three different values are entered. The top value (triangles) shows the expected proficiency standard for all schools in Minnesota (i.e., all students are to be at or above this score to be judged proficient). The next set of values (boxes) reflects longitudinal outcomes for the same cohort assessed in 1998, and again in 2000. These values show an increase of 117 scale score points, which is greater than the state average for students across a 2-year interval. The bottom set of values (circles) shows the quasi-longitudinal outcomes (i.e., the mean scale scores for students in the same grade in 1998, 1999, and 2000).

The current status method of accountability would note that, in each of the three years reflected on the graph, Lyndale fell below the state standard. The quasi-longitudinal method (comparing data from the last 3 years) suggest Lyndale is stagnant; that is, its students get the same scores in three consecutive year, and so it would lead to the conclusion that Lyndale is making little or no progress toward the state proficiency goal. In contrast, the longitudinal data show a gain of 117 scale score points in 2 years, showing that students who stayed in Lyndale made faster-than-average progress toward state proficiency standards.

Figure 1. Minnesota Comprehensive Assessment Data for Lyndale School



Thus, different methods of accountability may lead to different conclusions about school effectiveness. It should be noted that Minneapolis incorporates a mix of data analysis methods (including current status, longitudinal, and quasi-longitudinal methods), and a variety of indicators (including state test scores, attendance, Curriculum-Based Measurement, regular district tests, and other measures) to identify schools that are (and are not) effective.

Different accountability methods also yield dramatically different descriptions of special education outcomes (Bielinski & Ysseldyke, 2000). Current status and quasi-longitudinal designs show the gap between students with disabilities versus students without disabilities gets larger in higher grades. The increasing gap suggests students in special education fall further behind their general education peers. However, the longitudinal or value-added accountability method (which compares the same children to each other over time) shows the gap is constant, suggesting special education is as effective as general education in promoting academic progress. The apparent discrepancy between these accountability methods is due to asymmetrical migration of students. High scoring special education students exit special education, and low scoring general education students enter special education. This asymmetrical migration over grades leads to the erroneous impression that special education is holding students back, when in fact special education is adding the same value as general education.

Currently, most districts and states use current status methods in their accountability programs, due in large part to the increased expenses (i.e., annual testing in multiple grades, data analysis) of longitudinal and quasi-longitudinal methods. Although Linn (2001) views the emphasis on current status as unfortunate, others oppose longitudinal models on educational equity grounds (e.g., *Education Week*, 2001). That is, by adjusting school expectations for initial or prior student achievement, one could argue the accountability system allows lower expectations for low scoring students than for high scoring students. To return to the Lyndale School example, one could argue that praising the school for improving the cohort's academic achievement by 117 scale score points is tantamount to praising the school for producing a mean score that is below proficiency. Consequently, educational agencies (e.g., Minneapolis) strive to develop methods of accountability that reward progress, while at the same time ensuring that accountability methods demand high (and equitable) outcomes for all students (Linn, 2001).

STUDENTS WITH DISABILITIES AND EDUCATIONAL ACCOUNTABILITY

Of particular interest to many school psychologists is the issue of including students with disabilities in educational accountability programs. The 1997 amendments to the Individuals with Disabilities Act (IDEA 1997) mandate that states must include students with disabilities in their educational accountability systems, and include students with disabilities in the same system as students without disabilities whenever possible. Although the legislation does not specify an exact number, regulators assume that states should have 98% of all students participating in the standard accountability system. Given that most states classify 12% of the students in a given grade as disabled, it means that approximately 85% of students with disabilities must be included in state systems to meet the overall 98% participation goal.

Many educators serving students with disabilities may oppose students' inclusion in large-scale testing and accountability programs. After all, students with disabilities already endure more testing than other students (e.g., quarterly Individual Education Plan (IEP) goals, annual reviews, triennial evaluations), and are more likely to do poorly on accountability assessments, thus leading to academic demoralization. However, equity advocates argue that exclusion of students with disabilities from accountability programs would allow schools to ignore their needs, shunt them into low quality environments that would deny students access to the general curriculum, and reinforce low expectations. In short, equity advocates favor inclusion: If students are not counted, they don't count (Elliott, Braden, & White, 2001).

Assessment Accommodations

The primary mechanism for including students with disabilities in educational accountability programs is via testing accommodations. However, it should be noted that many students with mild disabilities need no accommodations, or need only physical accommodations (e.g., wheelchair accessible furniture). Still, many students will require accommodations because they have difficulties with literacy, regulating their behavior, or gaining access to written or spoken aspects of the assessment. There are four major domains of assessment accommodations (Thurlow, Elliott, & Ysseldyke, 1998):

1. Setting (e.g., accessibility furniture, isolated seating to avoid distractions, familiar environment to reduce anxiety)

2. Timing (e.g., extended time, rest breaks to avoid fatigue, dividing a long assessment into shorter periods)

3. Administration (e.g., signing or saying assessment directions, large print, cuing to direct attention)

4. Response (e.g., allowing oral, signed, pointing, or dictated responses, providing a keyboard or response console)

Generally, changes to test content (e.g., deleting a test, substituting a different test) are not acceptable for educational accountability purposes. Because accountability presumes all students take the same tasks, changes in the test itself are generally not allowed. One exception to this principle may be providing a version of a test aimed at a lower grade level (known as "off-level" testing) for students who have skills too low to be accurately assessed by the grade-level version used for accountability. However, most states do not allow off-level testing accommodations. School psychologists in particular should note that, although adjustments to test content are allowed (and even encouraged) in IEP and clinical assessments (see AERA, APA, NCME, 1999, chapter 9), they are not typically allowed in accountability assessments.

All states must allow accommodations for students with disabilities (see Office of Civil Rights, 2000, chapter 2), but often professionals are not clear about when, how, or what accommodations are appropriate. Most states provide guidelines, and some even provide approved lists of accommodations. Table 2 lists accommodations allowed by states (note that Table 2 combines setting accommodations under the single category of administration accommodations). However, educators should be thoroughly familiar with the specific requirements within their state, as not all states allow all accommodations.

Research and practice guidelines (e.g., Braden, 1999; Elliott, Braden, & White, 2001; Elliott, Kratochwill, & McKevitt, 2001; Thurlow, Elliott, & Ysseldyke, 1998) suggest the following principles to determine whether and what accommodations are appropriate:

1. The accommodation should be in place and used in the student's education setting for at least 4–6 weeks prior to the assessment. Accommodations that are unfamiliar to the student may not help, and even hinder, test performance.
2. Accommodations should address the student's access to the test (e.g., ability to read, hear, or see content, respond using an accessible medium, sustain attention to the test) rather than the skills targeted by the test. That is, it would generally be acceptable to read a mathematics test to a student with a reading disability to provide access to the mathematics, but would be inappropriate to read the same student a reading test (see Phillips, 1993, 1994, 1996, for more information about the distinction between "access" and "target" skills).

Table 2. Accommodations for students with disabilities

Presentation format

- Braille edition
- Large-print editions
- Templates to reduce visual field
- Short-segment testing booklets
- Key words highlighted in directions
- Reordering of items
- Use of spell checker
- Use of word lists/dictionaries
- Translated into sign language

Administration format

- Oral reading of questions
- Use of magnifying glass
- Explanation of directions
- Audiotape directions or test items
- Repeating of directions
- Interpretation of directions
- Videotape in American Sign Language
- Interpreter signs test in front of classroom/student
- Signing of directions
- Amplification equipment
- Enhanced lighting
- Special acoustics
- Alone in study carrel
- Individual administration
- In small groups
- At home with appropriate supervision
- In special education classes separate room
- Off campus
- Interpreter with teacher facing student; student in front of classroom
- Adaptive furniture
- Use place marker
- Hearing aids
- Student wears noise buffers
- Administrator faces student
- Specialized table
- Auditory trainers
- Read questions aloud to self
- Colored transparency
- Assist student in tracking by placing students finger on item
- Typewriter device to screen out sounds
- Extended testing time
- More breaks
- Extending sessions over multiple days
- Altered time of day that test is administered

Response format

- Mark responses in booklet
- Use template for recording
- Point to response
- Lined paper
- Use sign language
- Use typewriter/computer/ word processor
- Use Braille writer
- Oral response, use of scribe
- Alternative response methods, use of scribe
- Answers recorded on audiotape
- Administrator checks to ensure that student is placing responses in correct area
- Lined paper for large script printing
- Communication board

Other

- Out-of level testing

Reprinted from Office of Civil Rights (2000, Appendix C, Table 2). Council of Chief State School Officers, Annual Survey: State Student Assessment Programs, Washington D.C., 1999.

3. Accommodations should seek to reduce construct-irrelevant variance while retaining adequate construct representation (see Messick, 1995). This means that accommodations should seek to remove the influence of a disability that is irrelevant to the construct being assessed. For example, visual impairment may provide a construct-irrelevant influence on an individual's reading score when the test is administered using standard print. Providing the same test in large print, or allowing the individual to use technology that magnifies the print, would remove the construct-irrelevant variance from the assessment while maintaining construct representation (i.e., it still tests reading). This is similar to Phillips' use of "access" and "target" skills, but Phillips justifies her principles within a legal (rather than a psychological) framework.

4. Students who have access to, and are expected to acquire, the general education curriculum should participate in the general education accountability program. Conversely, students who do not come in contact with, nor are expected to acquire, general education curriculum (i.e., students with severe disabilities) should probably not participate in the general education accountability program.

5. Use prior testing as a guide to developing and implementing accommodations. Prior testing could include participation in large-scale assessment in earlier grades, and participation in classroom-based testing.

6. Document accommodations and the student's response to them. Documentation is generally required by states for eligibility (i.e., to be eligible for accommodations, the student must have an IEP or Section 504/ADA Individual Assessment Plan specifying the accommodations needed). However, documentation is also increasingly important for students who will participate in high school and post high school testing, such as college entrance, GED, and employment exams.

7. When in doubt, include the student in the assessment. There is no evidence that students with disabilities are harmed by participation. Although many educators may resist inclusion because they feel it will harm the student's self-esteem (e.g., the student may be frustrated or score poorly), they should also appreciate that exclusion from assessment may be detrimental to the student's self-esteem (e.g., the student may feel left out or humiliated to be separated from peers, or get the message that the student is "too stupid" to take the test). The limited research suggests that students with disabilities view tests and respond to them in the same way as their unimpaired peers (Elliott, Kratochwill, & McKevitt, 2001).

Alternate Assessment

IDEA 97 directs states to include students with disabilities in educational accountability programs even when they cannot be included in the general accountability system. When students with disabilities cannot be included in an exam, educators must develop an alternate assessment to evaluate the student's progress. Some states (e.g., Indiana) have aligned alternate assessment standards with content standards, so that a student's progress can be monitored from pre-academic through secondary school levels. Other states (e.g., Wisconsin) have not articulated continuous standards, and simply suggest alternate performance indicators for students not participating in the regular exams.

A thorough review of alternate assessment is beyond the scope of this chapter. Suffice it to say that educators must do whatever they can to include students with disabilities in the general accountability system, and when inclusion is not possible, develop an alternate assessment to monitor student progress. Given that states seek to include at least 98% of all students in the accountability system, educators should aim to include 85% (or more) of students with disabilities in the general education program. Alternate assessment is for those students whose educational goals are generally not aligned with the general curriculum or expectations, or about 15% of students with (the most severe) disabilities.

BEST PRACTICES FOR SCHOOL PSYCHOLOGISTS AND EDUCATIONAL ACCOUNTABILITY

Because most educational accountability programs are outside the domain of the school psychologist (i.e., they are generally administered by the state via administration, general education, testing and research, or counseling personnel at most school sites), school psychologists may wonder what their role in educational accountability could or should be. School psychologists have much to offer the system via their expertise in assessment, measurement, and understanding of individual differences and exceptionality. Consequently, participation in activities related to educational accountability may provide an avenue for school psychologists to gain visibility and influence in general education. The activities listed below are not exhaustive, but are intended to suggest roles for school psychologists related to educational accountability.

Local Policies Related to Educational Accountability Testing

In some states, there may be little or no flexibility regarding the use of test scores for high stakes (e.g., student promotion, retention, and graduation). However, some states direct school districts to develop policies, and most states provide some latitude in the interpretation and implementation of state policies. Because school psychologists understand the strengths—and the weaknesses—of assessment methodologies, they can help administrators and other educators develop, interpret, and implement ethical and appropriate policies for using test scores. Key considerations include basic principles of assessment (e.g., the use of multiple opportunities, methods, raters), and the implications of conjunctive versus disjunctive combinations of assessment data. There are a number of excellent references to guide policy development, interpretation, and implementation, including a report from the National Research Council on high stakes testing (Heubert & Hauser, 1998) and position statements from psychology (APA, 2001) and education (AERA, 2000) organizations (see Appendix A to locate these resources).

Table 3 provides an example of a promotion and graduation policy developed by a large district committee including three school psychologists. The proposed policy allows multiple forms of assessment to be used for making graduation decisions. The policy uses conjunctive criteria (e.g., the student must meet credit requirements in criteria 2 and 3 and 4 and 5) and disjunctive criteria (i.e., a student may graduate by meeting any one of criteria 2–5). Note that students may substitute expertise in one area for a deficit in

Table 3. Sample high school graduation criteria using high stakes tests

Students must earn required credit and ...

1. Must have a 2.0 or higher cumulative grade point average(GPA) in any two credits earned in classes aligned to the twelfth grade state Model Academic Standards in each of the core content areas (English, Mathematics, Science, Social Studies). A diploma will be granted to a student who meets the credit requirements and has at least a 2.0 cumulative GPA as above.
2. If a student has met the credit requirements for graduation but does not have a 2.0 GPA as above in each of the four core content areas, then the student must pass the High School Graduation Test (HSGT) in each of the content areas in which the GPA is less than 2.0. Students will be given four opportunities to pass the test, twice during both their junior and senior years on testing dates determined by the state department of education. A diploma will be granted to a student who meets the credit requirements and, for each of the four core content areas, has a 2.0 cumulative GPA as above or passes the HSGT.
3. If a student with a disability has a IEP that does not specify academic goals consistent with the state Model Academic Standards for the twelfth grade due to the student's functional level, but the student has met the credit requirements, the student will be granted a diploma.
4. If a student has met the credit requirements but does not meet the academic performance criteria as in number 1 above and does not pass the HSGT, the student may complete a district-defined portfolio evaluation of academic work that provides evidence the student has met state Model Academic Standards for twelfth grade. Portfolio evidence in the student's native language may be submitted. A student may use a portfolio to provide evidence of meeting twelfth grade state Model Academic Standards in *one* non-assessed area (e.g. Fine Arts, Foreign Language) in lieu of *one* of the assessed areas of the HSGT. The outcome of the portfolio review process may result in the granting of a diploma.
5. If a decision is made to deny graduation to a student who has the requisite number of credits over the objections of the student or parent/guardian, then that student may appeal the school's decision to the assistant superintendent responsible for that level, whose decision shall be final.

another area; students with IEPs may earn a diploma if they earn credit and are not working toward standard academic goals; and that non-English assessments are allowed to demonstrate proficiency.

Another example of influencing policy would be to develop multiple methods for assessing student work. School psychologists can draw on their assessment expertise to develop Curriculum-Based Measurement, portfolio, performance assessment, and other measures of student learning (see other chapters in this book). Then school psychologists may incorporate these measures into district promotion and graduation policies in addition to (or in lieu of) the state and district testing.

Promote Assessment Literacy

Despite the critical importance of assessment knowledge in the current climate of educational accountability, most educators are unable to understand and use assessment. Stiggins (1995) describes the body of knowledge needed to understand and use assessment as "assessment literacy," and notes most teachers lack assessment literacy. Again, school psychologists generally have strong expertise in assessment, and so could serve to promote assessment literacy among their general education colleagues. Examples include workshops on interpreting large-scale assessment results, introducing educators to test principles and content, pros and cons of assessments, and fundamentals of assessment (e.g., reliability, validity). School psychologists should also consider assessment literacy programs for students, their parents, and the general community. A truly strategic school psychologist would target an assessment literacy workshop to members of the local media shortly before the annual release of state or district data to help them understand and accurately report test data to the public.

Accommodations and Alternate Assessment

School psychologists can draw upon their knowledge of assessment, accommodations, and exceptionality in helping develop effective accommodations so that students with disabilities can participate in accountability assessments. Explaining the principles that lie behind assessment accommodation decisions can be very helpful to educators who know children well, but do not always share the skills and perspective needed to develop appropriate accommodation strategies. Other chapters in this volume may assist school psychologists in this activity. However, school psychologists should be particularly sensitive to the ways in which data reported in current status and quasi-longitudinal models may distort special education outcomes relative to the longitudinal or value-added accountability method.

Promote Opportunity to Learn

The impetus for educational equity begins with ensuring equal opportunity to learn. There are many sources to guide educators, schools, and districts to enhance all students' opportunity to learn, and there are other chapters in this volume that provide guidance on how to promote successful learning environments for all students. Other resources appear in the appendix to this chapter (e.g., Education Commission of the States, 1998) and in the references for this chapter (e.g., Porter, 1995). A key concept is to ensure educators provide students with low academic skills opportunities to engage in intellectually challenging curricula, while at the same time adapting curricula to individual differences. Methods to accomplish this include instructional modifications (e.g., scaffolding), adapting classroom assessments, and providing educational supports that retain challenging curricular aspects. One example of how school psychologists can help teachers enhance opportunity to learn is to adapt classroom assessments in ways that retain intellectual quality. Table 4 presents a suggested set of steps for adapting classroom assessments that will assist educators in adapting and modifying classroom assessments in ways that retain opportunity to learn.

School psychologists are also obligated to discourage activities that reduce opportunity to learn. Providing evidence on the consequences of retention, tracking, test preparation programs (see next section), and other activities that reduce children's opportunity to learn. Many of these issues are reviewed in other chapters in this volume, and school psychologists can use their knowledge to steer schools away from "reforms" that reduce OTL.

Give Psychology Away

This motto inspired many school psychologists in the late 1960s and 1970s to use their knowledge to

Table 4. Assessment accommodations framework: Principles for application

- *Students should not receive accommodations unless they are needed.*
  Many students with disabilities or low achievement can participate in challenging assessment tasks without any modifications. Just because a student has a disability does not mean the student needs assessment accommodations. If educators are unsure whether to accommodate a particular task or assessment, then they should encourage the student to try the task without accommodations. Offering the option for accommodations later (e.g., retaking or doing the task over) without penalty will encourage risk taking, which is an essential element of education reform.
- *Accommodations decisions presume target and access skills are clearly identified.*
  Teachers must clarify the intended targets of the assessment (the knowledge and skills the assessment intends to measure), and the skills that are required for access (the skills the student must have to understand or respond to the assignment). For example, reading skills are often targeted in language arts assignments, but are often access skills for mathematics, social studies, or science assessments.
- *Accommodations should address access, not target, skills.*
  An accommodation is appropriate if it allows students with disabilities access to the assessment task, but not if it changes the skill targeted by the assessment. This means an accommodation may be appropriate in one instance, but not another. For example, extra time might be an appropriate accommodation if the assessment targets reading comprehension skills, but it would be inappropriate if the assessment targets reading fluency skills.
- *Modify target skill complexity when access is insufficient to allow for reasonable assessment of skills.*
  Some students (usually those with severe disabilities) have skill levels that are so far below the level targeted in an assessment that inclusion in the assessment, even with successful access, is of no educational value. For example, a student with a severe cognitive delay may lack the language and concepts needed to understand a science task, even if the task is accommodated (e.g., reading the assessment, providing extra time, writing help) to allow the student access to the assessment task. In these cases, teachers should consider modifying the assessment to assess a less complex level of targeted skills.
- *Modifications to assessments should retain intellectual quality, even if they are modified to a simpler skill level.*
  When teachers modify tasks to assess a lower level of targeted skill, they should retain the assessment's intellectual quality (i.e., construction of knowledge, disciplinary inquiry via elaborated communication, and value beyond school). For example, a teacher should modify a science/mathematics assessment on rocketry by inviting the student to produce a simpler experiment (e.g., assessing Newton's third law of motion instead of studying the multiple effects of aerodynamics, gravity, acceleration, and propulsion). The teacher should not substitute an assessment with limited intellectual quality (e.g., labeling the parts of a rocket on a diagram, filling in the blanks, calculating answers to specific questions, matching definitions to terms).

Source: These recommendations are adapted from Braden, Schroeder, & Buckley (2001).

improve schooling and development for all children. The motto is equally relevant today, in that educators are being increasingly pressured to make decisions about curricula, instruction, and policies affecting children. High stakes testing has created a sense of urgency—but may have also inspired panic. Solid information about individual differences in intelligence, learning rates, disability, and instruction is essential to help educators select high quality responses to the high stakes pressure to reform. School psychologists can provide information that will help educators avoid selecting low quality, faddish, and superficial responses, and instead draw on research and science to guide educational changes.

Two examples in particular deserve mention. First, many educators are responding to testing pressures by adopting instructional strategies that emphasize superficial coverage of content to prepare for state exams (i.e., "spray and pray" or "drill and kill" approaches). This is extremely unfortunate, because it undermines the type of effective and meaningful school reform accountability programs are meant to encourage (see Newmann & Wehlage, 1995), and because it does not work. Although it is clear that schools and districts generally post gains for 2–4 years after adopting a new test, these gains typically level off and do not generalize to other tests—suggesting superficial changes have limited impact on achievement (Linn, 2000). Controlled research supports this conclusion by showing superficial coverage strategies produce standardized test results that are no better than high quality instructional strategies—and these superficial strategies produce much lower results on richer performance assessments (Baxter, Shavelson, Herman, Brown, & Valdez, 1993). Likewise, studies in the Chicago Public Schools (e.g., Newmann, Bryk, & Nagaoka, 2001; Smith, Lee, & Newmann, 2001) show that students who receive high quality intellectual instruction do better on standardized tests than students who receive low quality, coverage-oriented instruction. Some key sources that may be helpful in presenting this message are the report of the Center on Organization and Restructuring of Schools (Newmann & Wehlage, 1995), and the Research Institute on Secondary Education Reform—Youth with Disabilities publications and website.

A second example of giving psychology away is sharing knowledge about test preparation programs and strategies. Although the majority of research addresses preparation for college entrance exams such as the SAT or ACT, there is some work addressing K–12 achievement tests. The results of both lines of research converge in suggesting test preparation programs produce small or no improvements in test scores (Chicago Public Schools, 1987; Cushing, Sabers, & Kerrins, 1989; DerSimonian & Laird, 1983; Ehrmann, 2000; Powers, 1993; Scholes & Lain, 1997). In those studies showing small positive effects, mathematics scores tend to be increased more than do language arts scores (Deaton, Halpin, & Alford, 1987; Federal Trade Commission, 1979; Powers, 1993; Reynolds & Oberman, 1987). However, a careful examination of the psychological literature would suggest that reforming education to engage students in intellectually challenging content would be more effective than spending time and money on test preparation programs. Genuine reforms not only improve test scores—they improve learning and teaching.

SUMMARY

Accountability for student achievement currently enjoys strong popularity, and is supported by state and federal education laws. Both U.S. political parties oppose social promotion (i.e., the advancement of students to higher grades based on age rather than demonstrated academic accomplishments), and there is broad political consensus that high school graduates should clearly demonstrate mastery of academic standards. Consequently, accountability testing for low, medium, and high stakes is likely to continue or increase. The question confronting most educators is not whether to use high stakes testing to make decisions, but rather how to use and respond to high stakes testing in ethical and appropriate ways. School psychologists can use their knowledge of assessment, learning, individual differences, and broad psychological principles to help educators, administrators, and parents understand and respond to educational accountability mandates, and the consequences that accrue to high stakes tests.

Best Practices in School-Community Partnerships

OVERVIEW

> I am interested in attempts to develop the notion of a community system of services, mutually interdependent, seeking to locate, evaluate, and serve the interests of families and children in trouble. The concepts of accountability and responsibility provide the motive power for some sacrifice of traditional prerogatives in the face of community objectives.
>
> —*Eleanor Roosevelt*

The message conveyed in this quote by Eleanor Roosevelt still rings true with many educators, officials, and policy reformers today. Interestingly, notions related to community, coordination, and collaboration have been touted for several decades. Such constructs hold promise for addressing the growing challenges facing societal structures in contemporary America. Symptoms of social dysfunction are apparent in several contexts, including those at the school, family, and community levels. Accordingly, greater degrees of responsibility are being placed on the school for addressing the diverse needs of students. However, it is unrealistic to expect schools alone to deal with the growing array of problems placing children at risk. It is clear that schools alone cannot provide all the services that children need to learn and achieve. Similarly, it is not possible for community-based entities to meet the challenges in isolation. The formation of school-community partnerships that are proactive, responsive, and actualized in specific contexts appears to be a viable avenue to begin addressing large scale problems in a comprehensive, systemic way.

The word "community" is derived from the Latin word "communis," meaning "common." For a common group or entity to be considered a "community," shared cultures, identities, responsibilities and values are essential. Beyond a geographic familiarity, community connotes "a place of reference and belonging" (Chaskin & Richman, 1993, p. 207).

Definition of School-Community Partnerships

School-community partnerships involve "an interactive exchange of ideas, resources, services, and expertise between educational and non-educational agencies in a variety of settings that mutually address the needs of students and the community as a whole" (Welch & Sheridan, 1995, p. 353). Generally speaking, such collaborations utilize community resources together with school resources to strengthen schools, families, communities, and student learning and development. According to Nelson, Amio, Prilleltensky, and Nickels (2000), "through positive relationships, groups of diverse stakeholders create something larger than a specific… program: they build a sense of community, a positive social climate, and an ethos of change" (p. 124).

The notion of schools and communities as "partners" implies several distinct qualities about the relationship. *Defining characteristics* of school-community partnerships are listed in Table 1 and explored briefly below.

INTERACTIONS AMONG PARTNERS ARE COLLABORATIVE

Importantly, when schools and communities come together to truly partner around the needs of their shared constituencies, collaborative patterns of interaction are paramount. *Collaboration* is characterized by a diversity of individuals and vantage points working together as co-equal parties, sharing in the identification of goals and solution of problems, and forging trusting relationships wherein resources, power, and responsibilities are shared. According to Minke (2000), "collaboration encompasses far more than simply working together; it involves fundamental restructuring of *how* individuals or agencies work together" (p. 379; emphasis in original). It implies more than individuals or groups coming together to cooperate or coordinate services; rather, it implies that boundaries among agencies are blurred, and that resources and responsibilities are jointly shared in the development, implementation, and evaluation of program objectives.

RELATIONSHIPS ARE COOPERATIVE, INTERDEPENDENT, AND BALANCED

Schools and agencies/community groups share equally in identifying, addressing, and solving problems. Likewise, program goals are mutually determined. With shared ownership comes a shared responsibility for the child's success, with the recognition that outcomes achieved in the context of the partnership are uniquely superior to those achieved by any party in isolation. The status of educators and community members is complementary, recognizing the benefits of unique contributions that each can make. Finally, each member of the partnership has generally equal opportunity in decision making.

MAINTENANCE OF A POSITIVE RELATIONSHIP IS A PRIORITY

The importance of relationship building in school-community partnerships cannot be overstated. McDaniel, Campbell, and Seaburn (1995; cited in Minke, 2000) aptly stated "the top three ingredients for effective collaboration … would be relationship, relationship, relationship" (p. 296). Failure to develop relationships can undermine the formation of successful partnerships.

In school-community partnerships, personal needs and goals are put aside to allow the needs and goals of the group to take precedence. Minke (2000) discusses the notion of "connected relationships," wherein partners "believe that the other person in trustworthy, is working toward a mutually held goal, and has positive regard for you" (p. 388). Additionally, all parties (school personnel, agency representatives, community members) believe that the partnership and the anticipated outcomes are worthy of the expenditure of the time and energy necessary for its maintenance.

RELATIONSHIP OCCURS IN AN ECOLOGICAL CONTEXT, WITH STUDENTS AT THE CENTER

School-community partnerships are based conceptually on the notion that students, families, schools, and communities are all members of interrelated ecologi-

Table 1. Characteristics of school-community partnerships

- Interactions among partners are collaborative.
- Maintenance of a positive relationship is a priority.
- Relationships are balanced.
- Relationships are cooperative and interdependent.
- The relationship occurs in a context with students at the center.
- Actions between schools and agencies/community groups are flexible, responsive, and proactive.
- Differences in viewpoints and perspectives are seen as strengths, not hindrances.
- There is a commitment to cultural diversity.
- There is an emphasis on outcomes and goal attainment.

cal systems (Bronfenbrenner, 1979; Christenson & Sheridan, 2001). Difficulties experienced by children and families do not represent inherent deficits. Rather, difficulties are the result of a mismatch among the individual or family and the environmental contexts (e.g., schools, neighborhoods, communities) within which they function. Services are therefore aimed at learning *from* the individual and family, and organizing programs in ways that are beneficial and viable within the interconnected family, school, and community systems. Although programs may be implemented at several levels (including the environmental or ecological levels), main attention is always given to the potential benefits and outcomes for students. That is, school-community partnerships are student-centered (Welch & Sheridan, 1995).

ACTIONS BETWEEN SCHOOLS AND AGENCIES/COMMUNITY GROUPS ARE FLEXIBLE, RESPONSIVE, AND PROACTIVE

The manner in which school-community relationships are defined and the actions that are developed vary depending on the unique school-community context and situation. Services and programs are useful only to the extent to which they are responsive to needs within a particular context. From one program to the next, community members and educators will be involved in very different ways depending on the nature of the contact, the needs presented, the goals for the program, the resources available, and a host of other relevant factors.

DIFFERENCES IN VIEWPOINTS AND PERSPECTIVES ARE SEEN AS STRENGTHS, NOT HINDRANCES

A main feature of school-community partnerships is the diversity of experiences, skills, perspectives, and views that are brought to bear on problems and programs. The respective vantage points of educators, agency representatives, and community members enhance the understanding of a situation and the opportunities and resources available for solutions. The unique knowledge, resources, talents, and expertise that educators and community members/agencies bring to a situation enhance the potential outcomes for students.

THERE IS A COMMITMENT TO CULTURAL DIVERSITY

When schools and communities join to form partnerships, services are delivered in a way that is respectful of the cultural values and traditions that community members and educators bring with them. Discrimination based upon language, race, ethnicity, class, gender, and sexual orientation is detrimental to a program's success. Services that are sensitive to important cultures and traditions in the community are most likely to be effective. Diversity is not only important for a program's implementation, it is also important in carrying out research and program evaluation activities.

THERE IS AN EMPHASIS ON OUTCOMES AND GOAL ATTAINMENT

School-community partnerships have clearly specified goals, and progress toward goals is closely monitored through data-based decision-making processes. Programs are not instituted simply because they are available; rather, they are considered carefully with attention to the degree to which they fit within the overarching priorities of the partnership. Goals and objectives that are identified are outcome-based, and include problem resolution or management, prevention, and development of skills and competencies.

Objectives and Benefits of School-Community Partnerships

In addition to these defining characteristics, there are several objectives of school-community partnerships. Objectives related to the partnership process, as well as the content of the programs can be elucidated. "Process" objectives include (a) combining and sharing resources, expertise, and efforts to achieve a commonly defined mission; (b) empowering educational and community personnel to access, refine, and/or develop new, creative approaches to tasks and problems; (c) developing and refining professional skills of all parties through the exchange of ideas, knowledge, and expertise; and (d) enhancing educational services for all students (Sheridan, 1995).

Objectives related to the content of a partnership program are also evident. Some school-community partnerships are formed to address academic or educational needs. *Educational objectives* focus on facilitating the academic and development growth of students and their families. An example of a partnership program that espouses an educational mission is literacy training for adults staffed by community volunteers, offered in a school's media center in the evening hours. *Social and health objectives* are evident in school-community partnership programs that are concerned with physical, health, and mental health needs of students and families. For example, anti-drug or violence programs, teen pregnancy groups, and nutritional classes represent programs that have at their center students' health and well being. *Vocational objectives* target job and career needs of students by providing career education and on-the-job training in or outside of the school building (Welch & Sheridan, 1995). Such programs often focus on teaching students skills or trades to use in the community following graduation.

It should be noted that some partnerships between schools, agencies, and community members form with clear objectives that encompass two or more objectives described above. There is often overlap in the objectives associated with programs. For example, some drug prevention programs may combine health/mental health objectives (e.g., remaining drug free, finding alternatives to drugs, coping with anxiety or depression) with those associated with academic support to assist a student to complete high school, and vocational training to teach functional job skills. Likewise, linkages formed among multiple community agencies (e.g., schools, mental health centers, health departments and clinics) in contemporary comprehensive service models illustrate coordinated efforts to address several shared objectives.

There are several benefits associated with school-community partnerships. According to the National P. T. A. (2000), "when schools and communities work together, both are synergistically strengthened and make gains that outpace what either could accomplish on its own" (p. 132). Although there are problems inherent in the empirical studies investigating school-community partnerships (e.g., poorly described models, varied procedures for establishing partnerships, lack of clearly defined constructs), it is generally agreed that positive outcomes for students, parents, teachers and administrators, and community agencies and organizations are achieved. *Students* benefit by gaining increased skills due to enriched curricular and extracurricular activities, enjoying improved positive relationships with adults other than parents and teachers, and acquiring an enhanced sense of value and belonging to the community. It is reported that when involved in partnerships, *parents* gain an awareness of the community's contributions to the school, develop a sense of connection with other families in the community, and gain knowledge of and use local resources to obtain needed services and improve their parenting skills. *Teachers and administrators* reportedly gain knowledge of and become involved in the social and community service referral process, develop skills for working with business partners, community volunteers, and mentors and gain knowledge of and use community resources to enrich their classroom instruction. Finally, *community organizations and agencies* gain improved access to community resources, form connections between business and prospective future employees (students), and gain a greater sense of purpose by contributing their knowledge and skills to students (National PTA, 2000).

BASIC CONSIDERATIONS

School psychologists can be instrumental in promoting partnerships between schools and communities. In a comprehensive chapter, Minke (2000) offered suggestions for school psychologists interested in establishing and participating in school-family-community partnerships. She indicates that school psychologists could (a) be an effective role model by examining their own thinking, using effective communication skills and using solution-oriented problem solving strategies; (b) create opportunities for relationship development; (c) attend to resource development by assessing the environment and developing a resource coordinating team; (d) set priorities and collaborate judiciously; and (e) be persistent. Below some additional considerations are provided for getting started and maintaining the process.

Getting Started in the Process

School psychologists interested in establishing school-community programs may question how they can make it work in their schools. Although every situation is unique, there are common elements necessary to get started. Across several sources and model programs, similar suggestions are made for establishing an environment that is prepared to implement a program. These include (a) cultivating a relationship with the principal; (b) reaching out to parents, teachers, and other partners; (c) focusing on children and results; and (d) establishing short-term goals.

CULTIVATING A RELATIONSHIP WITH THE PRINCIPAL

Principals play a pivotal role in schools, and can be instrumental in the success of partnership programs. Cultivating a positive relationship with the principal of a school is important for several reasons. Positive, trusting relationships with school leaders allow school psychologists to promote broadened, effective roles and to establish important support programs in schools. They can integrate and oversee the programs' services, and generate enthusiasm and commitment among teachers and other school personnel. Partnerships that are fully integrated into the school and accepted by the principal and teachers are the most successful. When garnering support of the principal, school psychologists can emphasize how a partnership among the school and local community agencies or groups can help support teachers' ability to teach; provide students with expanded learning opportunities; work to increase parent involvement; and provide additional support to the school.

REACHING OUT

School psychologists are in unique positions in schools that allow them access to individuals both within and outside of the formal walls of the school building. This places a unique responsibility on them to reach out to teachers, parents, and other potential partners working in the school or neighborhood. Although teachers' responses to school-community partnerships will vary, it may be possible to find some teachers who demonstrate a willingness to consider their role as going beyond the classroom and embrace new strategies to reach their students. Identifying a small number of teachers with whom to start, inviting them to serve on the school-community team, and informing them of the importance of their perspective and expertise on the team and in the program may be sufficient to establish an important teacher presence.

It is also important to identify parents who can generate ideas and assistance in the establishment of school-community linkages. Some parents may already demonstrate an awareness of the importance of their role in the educational success of students. They may have potential as leaders for initiating broader levels of parent and community support. Likewise, school psychologists or others within the school can institute a parent-outreach initiative aimed at reaching out to and soliciting input from parents about goals and aspirations for their children. Parents are more likely to be involved if they believe they can make a difference in what happens for their children.

Within local communities there are several partners whose resources are already being used to support children and families. Likewise, there are often personnel within schools whose roles overlap with each other, or with individuals in the community. Frequently, staff in a school and in community agencies performs similar functions for the same youth without considering how their work is related or effective in connecting children and families to the resources they need. When reaching out to communities, the roles of school nurses, social workers, counselors, psychologists, and other support staff should be considered. Efforts can then be directed toward determining how overlapping resources can be allocated, shared, or diversified to meet needs rather than perform functions.

FOCUSING ON CHILDREN AND RESULTS

When getting started, the overall purpose and goal of school-community partnerships must remain central. The focus on children and results for children should be the driving force at each step of program planning and implementation. Partnerships between school and community can serve many practical functions. However, their main purposes are to enhance the learning and development of children. Questions that can structure discussions and decisions may include *What do we want for the children in our school and their families? What do we know about their education and well being now? What skills or resources do they need to successfully meet the goals we have for them? How will we know if we have made an impact?*

ESTABLISH SHORT-TERM GOALS

Although the scope of partnership programs can be large, it is strongly encouraged that smaller objectives be identified to make the task manageable, and to allow for the identification of success along the way. It is helpful to identify an issue or task that the partnership team can work on together where there is a likelihood of success. Examples may include organizing and hosting a family night for students and parents, conducting a health fair, or offering a class or in-service on accessing free community resources of interest or need to families. Celebrating small successes in the program can strengthen its vitality and contribute to its overall effects in a systematic way.

Maintaining School-Community Partnerships Through Interdisciplinary Action Teams

Just as schools cannot alone address the increasing needs of children and families, any one school professional is insufficient to institute change necessary to invoke broad-based partnerships involving schools, families, communities, and other stakeholders. It is generally recognized that the formation of *interdisciplinary action teams* (or resource-oriented teams) (Adelman & Taylor, 2000) can facilitate the work surrounding the design, implementation, and evaluation of school-community partnerships. Such teams "provide essential mechanisms for starting to weave together existing school and community resources and encourage services and programs to function in an increasingly cohesive way ... (they) are also vehicles for building working relationships and can play a role in solving turf and operational problems; developing plans to ensure availability of a coordinated set of efforts; and generally improving the attention paid to developing a comprehensive, integrated approach for addressing barriers to student learning" (Adelman & Taylor, 2000, p. 21). Representatives of several programs, agencies, services, and constituencies can be included on the team. Likewise, it is important to involve several professionals from within school settings, such as school psychologists, social workers, counselors, administrators, health educators, and others who have different areas of expertise that can be used to contribute to program development.

The precise functions of resource/action teams can vary, depending on the unique situations and contexts within which individual teams function. Among the various responsibilities for which teams can be responsible are analyzing existing activities and resources; evaluating structures and procedures currently in place; assuring quality in practices related to referral and case management; facilitating effective channels for communication among staff, community, and families; and exploring ways to enhance resources (Adelman & Taylor, 1999).

Several qualities have been identified as important for relationships on school-community action teams. These include mutual respect, trust, clear communication, self-disclosure, and friendship (MacGillivary & Nelson, 1998). Likewise, early objectives of action teams involve creating a welcoming and friendly climate for partners; clarifying a mission to guide the process; deriving working principles (ground rules); and identifying strengths of different partners and approaches (Nelson et al., 2000).

Although interdisciplinary teams are essential to integrating services and developing effective school-community partnerships, school psychologists are in a unique position to be effective participants and leaders. Knitzer (1997) points out that psychologists are well suited to perform several key functions that are essential to service integration. First, school psychologists are uniquely qualified to take a leadership role in many activities that are essential for the development of successful integrated school-community partnerships such as developing a shared vision, decision-making forum, and framework for problem solving. Second, given their knowledge of clinical and developmental issues, school psychologists may ensure that integrated programs and partnerships take into account current psychological research on child and family development. Third, school psychologists have a large role to play in the area of outcome research and program evaluation. This is an essential area as much of this research has been poorly conceived and executed in the past, limiting our knowledge of what makes a successful school-community partnership (Knitzer, 1997).

BEST PRACTICES IN SCHOOL-COMMUNITY PARTNERSHIPS

Although there is limited empirical research investigating school-community partnerships, several authors (e.g., National PTA, 2000; Nelson et al., 2000; Minke, 2000; Welch & Sheridan, 1995) offer useful guidelines and steps for establishing school-community partnerships to assist in the development of effective school-community partnerships. Following are guidelines for maximizing the success of school-community partnerships and steps for their implementation.

Guidelines for Maximizing the Success of School-Community Partnerships

Knowledge of basic guidelines or strategies can facilitate the development and implementation of school-community partnerships. Some helpful guidelines are listed in Table 2. First, when establishing school-community programs, *plan them carefully and systematically*. Effective partnership programs are organized in a way that is responsive to the needs of their constituencies, and thoughtful in their design. Second, *manage the partnership carefully*, with committed leadership. Strong, effective leadership should guide the processes and procedures associated with program implementation. Third, *build flexibility into your program* (Sheridan, 1995). This refers to the ability of a school-community program to respond to changing constituent needs, and flexibility in financial and funding policies.

Another important guideline in establishing school-community partnerships is to *involve participants in all phases of the program*. Individuals from groups including families, students, school personnel, neighborhood groups, local clubs, and other community stakeholders can be involved in the development, implementation, and evaluation of school-community programs. Participant-driven programs are more likely to yield higher levels of ownership and commitment than those administered in a top-down fashion.

A fifth guideline suggests that implementers *incorporate training and professional development into the program's structure*. Training that focuses on interdisciplinary competencies, as well as procedures for program implementation and evaluation, is paramount. Such training can allow individuals from across professional domains and community agencies to learn collectively strategies for effective communication, problem solving, conflict management, and other processes associated with collaboration. It can also provide opportunities for the program implementers to learn procedures for the day-to-day operation and management of the partnership program.

Sixth, it is encouraged that program planners *incorporate new, innovative techniques for evaluating outcomes into the program's design*. Traditional program evaluation methods have not proven effective in assessing the success of complex school-community partnerships. Evaluating collaborative programs is very complex and requires new ways of approaching assessment. Approaches such as participatory action research and related qualitative methodology seem particularly fruitful in this area (Kratochwill & Stoiber, 2000; Nastasi, 2000).

Steps for Establishing School-Community Programs

Nelson et al. (2000) provide useful steps for creating and implementing partnership programs, which are presented in Table 3. These include creating partnerships by including community members and creating a welcoming environment; clarifying values and deriving working principles; identifying and merging respective strengths of the partners; defining and analyzing the problem or task collaboratively; develop-

Table 2. Guidelines for establishing effective school-community partnerships

- Plan partnership program carefully and systematically.
- Manage the partnership carefully, with committed leadership.
- Build flexibility into the partnership program.
- Involve participants in design, implementation, and evaluation.
- Incorporate training and professional development into the program structure.
- Use new, innovative techniques for evaluating outcomes of the partnership program.
- Be an effective role model.
- Create opportunities for relationship development.
- Attend to resource development.
- Set priorities and collaborate judiciously.
- Be persistent.

ing a program and ensuring the availability of resources; and evaluating the steps and outcomes collaboratively. Along with tasks and processes associated with each step, important challenges for school psychologists are enumerated.

Programmatic steps of a partnership process are those associated with problem solving models in general (see Tilly, this volume). First, it is essential to conduct a *school-community needs assessment* to identify particular problems, needs, and priorities. It is strongly recommended that all participants (including school personnel, community representatives, families, students, and other relevant stakeholders such as clergy, neighborhood clubs, or local government) engage in a needs assessment to increase their ownership and commitment to the program that is ultimately developed (Durlak, 1997; Johnson, Malone, & Hightower, 1997). Needs assessments can be conducted through interviews, surveys, or group meetings (e.g., focus groups). Whatever format is used, concrete

Table 3. Steps in the implementation of partnerships for program implementation: tasks, processes and challenges

Steps	*Tasks and Processes*	*Challenges for School Psychology*
Create partnerships.	• Include community members and service providers from the community with whom the intervention is to take place • Create a welcoming and friendly climate for partners.	• Abandon the role of the expert and share power with partners. • Reduce barriers to participation for partners. • Learn to value and build relationships.
Clarify values and vision and derive working principles.	• Collaboratively clarify values and vision to guide the program. • Derive working principles (ground rules) for how the group and program should work.	• Engage in self-reflective analysis of personal values. • Be open to being challenged by partners. • Be aware of value incongruence and strive to reduce it.
Identify and merge the strengths of different partners and approaches.	• Identify and build on strengths of different partners. • Merge deductive/nomothetic and inductive/experiential approaches to planning and implementation.	• Work to overcome self-doubt and mistrust of community members. • Value the experiential knowledge of community partners. • Find common ground and respect differences to bridge the worlds of community members and professionals.
Define the problem collaboratively.	• Collaboratively define and analyze the problem in terms of risk and protective factors at multiple ecological levels. • Focus on the strengths of the community.	• Reconcile differing views and build consensus regarding a prevention program model.
Develop the program collaboratively.	• Collaboratively decide on what type of program to implement. • Ensure that necessary hardware and software are available for program implementation.	• Educate and train partners in research and evaluation. • Be open to learning new perspectives and ways of working from partners. • Clarify roles.
Research and evaluate collaboratively.	• Use both deductive (quantitative) and inductive (qualitative) approaches in program evaluation. • Research and evaluate each of the steps.	• Educate and train partners in research and evaluation. • Learn to see community members as valuable partners in research and evaluation. • Clarify roles of partners.

Adapted with permission of Lawrence Erlbaum, Inc. From Nelson, G., Amio, J. L., Prilleltensky, I., & Nickels, P. (2000). Partnerships for implementing school and community prevention programs. *Journal of Educational and Psychological Consultation, 11*, 121–145.

and specific information should be elicited. Although the needs assessment process may be time consuming, it is critical in maximizing the overall meaningfulness and effectiveness of partnership programs (Welch & Sheridan, 1995). When paired with an analysis of existing programs and resources, data from the needs assessment can provide "a sound basis for formulating strategies to link with additional resources at other schools, district sites, and in the community and to enhance use of existing resources" (Adelman & Taylor, 2000, p. 21). Only then can programs be developed that are responsive to the needs of the community.

One outcome of the needs assessment is the *establishment of goals and objectives for the school-community partnership*. Through the investigation of needs shared by the school, community, and constituencies (e.g., students and families), specific priorities and objectives for school-community programs can be identified. Goals will further assist in the articulation of a program's scope and purpose. It is recommended that members of school-community teams identify both short-term and long-term goals and objectives to structure and organize their efforts. Desired outcomes should also be identified to assist in subsequent ongoing evaluations of the program. Such accountability is important to ensure continued progress toward established goals.

Second, an *ecological analysis* should be conducted to identify factors that contribute to or maintain the current situation/problem, and resources that are available to contribute to program implementation. Issues that contribute to the need can be explored, including characteristics of the community, school, families, and children. Likewise, human, material, technological, financial, and informational resources that can help address the issues should be identified.

Third, members of the school-community team can together *develop a plan* to meet the needs and begin working toward shared goals. Collaborative problem-solving approaches encouraging innovative solutions can be explored when resources are brought together. As program plans are developed, it is recommended that one individual be responsible for ensuring that the details of the program are clear to all participants, the strategies are followed with integrity, and communication remains open. In some situations, a coordinator whose time is allocated specifically for oversight of the program may be important.

Specific written guidelines in the form of a management plan maximize smooth operation of the program. Implementing the school-community program requires that implementers engage in practices consistent with program design and in a manner that is responsive to the needs of constituencies and stakeholders. Effective and responsive programs emphasize accountability for results, rather than blind adherence to process. Finally, ongoing *formative and summative evaluation* is important to monitor the effects of the program in relation to predetermined goals. Shared decision making and implementation lead to shared accountability for results.

The guidelines and steps recommended are useful for a variety of types of school-community partnerships. In practice, school-community partnerships have evolved to address many diverse needs of students, families, and communities. The types of programs currently being developed demonstrate much innovation and often challenge traditional notions of how best to serve our nation's youth. Areas commonly targeted by school-community partnership programs include health and mental health, family needs, academic achievement, drop-out prevention, and gang membership. Likewise, increasing concern about the vulnerability of youth in today's society has prompted increased interest in developing collaborative programs to address concerns such as youth violence, substance use/abuse, sexual activity, stress, and suicide (Dryfoos, 1997). Below two areas often addressed in school-community partnerships—mental health and violence prevention and intervention—are discussed.

School-Community Partnerships and Mental Health Programs

Although programs involving school-community partnerships have been developed to address a diverse number of issues, it has been suggested that "when school-based clinic providers are asked what the largest unmet need is among their clients, they most frequently mention mental health counseling" (Dryfoos, 1997). Almost 3 million children and adolescents receive some kind of mental health service each year in North America (Weisz & Weiss, 1993). In addition, the number of youth in need of these services appears to continue to grow. Increased school-community collaboration offers an effective avenue to meet these growing needs and provide accessible, timely, affordable, and effective mental health services.

A project funded by the National Association of School Psychologists (NASP) and the Children's Services Committee identified essential components of exemplary school-community mental health programs in which school psychologists were involved (Nastasi, Varjas, Bernstein, & Pluymert, 1998). The results of this study indicate that school psychologists were not often mentioned in the mental health literature; however, it was emphasized that school psychologists may play a critical role in the development, implementation, and evaluation of school and community-based mental health programs. Although school psychologists are well trained to successfully address a wide range of mental health needs and coordinate school-community partnerships to meet the mental health needs of students, they frequently spend the majority of their time performing assessments to determine special education eligibility (Gutkin & Conoley, 1990). This leaves little time left for the provision of mental health services.

To make strides in the area of mental health service, school psychologists must strive to expand the range of services they provide. Educating school administrators, policy makers, parent groups, and community agencies about their training and competencies is essential (Sheridan & Gutkin, 2000). Each day, in every school in the nation, there are countless opportunities for school psychologists to get involved in mental health issues. To begin the process of change, school psychologists must above all else take action. Becoming involved in both direct and indirect service provision such as consultation, counseling, family therapy, parent training, and crisis intervention will place school psychologists in a better position to establish school-community partnerships to address mental health needs in schools.

Six key criteria that reflect best practices in developing successful mental health programs were identified through this project. Because these have been described elsewhere in this chapter, they will not be explored in detail here. The criteria of exemplary programs, as suggested by Nastasi et al. (1998), include (a) integrating theory, research, and practice; (b) ecological-developmental model; (c) collaborative-participatory model; (d) continuum of services; (e) program evaluation; and (f) school psychologist involvement.

In addition, school psychology training programs must work to change perceptions of the types of services school psychologists are able to offer.

School-Community Programs and Violence Prevention and Intervention

With the increase in school violence in our nation's schools, school psychologists are asked to develop and implement prevention and intervention programs to combat school violence. Given the seriousness of school violence and the different forms that violence can take (isolated episode, bullying, assault), it is unrealistic to assume that one individual or even a small group of individuals can successfully impact the problem of school violence. The complexity of violent behavior requires an ecological approach to violence prevention. In fact, programs with only classroom-based components reported weak results (Howard, Flora, & Griffin, 1999). Additionally, family, community and peer risk factors (i.e., family conflict, violence in the community, deviant peers) primarily impact youth aggression outside of school (Reese, Very, Simon, & Ikeda, 2000). Therefore, the need to coordinate school and community efforts in violence-prevention programs is paramount.

Youth violence must be viewed from a broad, ecological perspective in order to develop effective intervention programs. A framework for understanding the complexity of youth violence has been proposed (Howard et al., 1999). This framework depicts the three areas in which youth function (school, home and community) and the different environs in which youth interact (information, social, and physical; see Figure 1). An effective school-community partnership to combat youth violence will address the complex and interactive nature of youth violence. The programs outlined below (Multisystemic Therapy (MST) and the Bullying Prevention Program) have demonstrated effectiveness in targeting youth violence at both ends of the continuum (chronic violent offenses to bullying), and represent model school-community partnerships.

It has been estimated that there are more than 300 violence-prevention programs available (Howard et al., 1999). Given that early antisocial behavior is a risk factor for subsequent delinquent behavior (Far-

rington, 1989) and bullying behavior may be a precursor to more serious forms of antisocial behavior (Olweus, 1993), we have chosen to review two empirically validated programs—MST and the Bullying Prevention Program—that focus on these areas and emphasize school-community partnerships. Both programs are included as one of the 10 model "Blueprints for Violence Prevention" programs that have been published under the Center for the Study and Prevention of Violence at the University of Colorado at Boulder (Elliott, 1999).

MULTISYSTEMIC THERAPY

MST (Henggeler, Schoenwald, Borduin, Rowland, & Cunningham, 1998) is designed to reduce delinquent behavior in chronic violent offenders. The strength of MST is that it is based on Bronfenbrenner's (1979) social-ecological theory and involves the family, community, peer group, and the youth in treatment. MST targets violent, chronic, or substance abusing male or female juvenile offenders, ages 12–17. These youth are at risk for out-of-home placements, school failure, and social failure. The goal of MST is to help these youth in their natural setting in order to facilitate change. The major thrust of MST is to empower caregivers with the skills and resources needed to raise difficult teenagers. Additionally, youth are taught coping skills in order to deal with family, peer, school, and community problems.

MST is a comprehensive, child-centered, community- and family-based treatment designed to ameliorate serious antisocial behavior in juvenile delinquents (Henggeler et al., 1998). This therapeutic approach views the individual's functioning from a social-ecological perspective. As such, interventions are designed to occur at the individual, family, peer, school, and community levels. MST focuses on the importance of interagency linkages and collaboration. The juvenile justice system, welfare, mental health, family court, and the schools work together to develop a systematic plan for rehabilitation versus punishment of adolescent offenders.

The primary goals of MST are to (a) reduce youth criminal activity, (b) reduce substance abuse and other types of antisocial behavior, and (c) decrease rates of incarceration and out-of-home placements. A home-based model of service delivery is the foundation of MST. This facilitates access to treatment and allows for intensive services to be provided. Additionally, a home-based model of service delivery helps ensure treatment maintenance.

The average duration of MST is 60 contact hours over 4 months. Individual family needs determine the frequency and duration of services provided. Therapists are divided into teams consisting of three to four therapists. A treatment team may provide services for approximately 50 families per year. Weekly supervision is provided to therapists and a high level of clinical support is critical for successful implementation. Table 4 outlines the key characteristics of the MST model.

MST has been shown to be effective in the treatment of serious juvenile offenders. Evaluations of MST have shown (a) reductions of 25–70% in long-term rates of re-arrest, (b) reductions of 47–64% of out-of-home placements, (c) extensive improvements in family functioning, and (d) decreased mental health problems for serious juvenile offenders (Borduin et al., 1995).

In MST, Ph.D. school psychologists will most likely function as clinical supervisors of MST therapists. Specialist-level school psychologists will likely be a part of the assessment team of the child or adolescent referred to MST. One barrier to successful MST is high family-school conflict (Henggeler et al., 1998), and school psychologists who are trained in home-school consultation are uniquely suited to help reduce family-school conflict in order to facilitate the implementation of MST. Thus, school psychologists can function as supervisors, assessors, and consultants in the delivery of MST.

BULLYING PREVENTION PROGRAM

Previous research has found that 75% of school-aged youth report having been bullied at least one time during their school years (Hoover, Oliver, & Hazler, 1992). Therefore, bullying may be one of the most pervasive forms of violence in our schools (Batsche & Knoff, 1994). The Bullying Prevention Program (Olweus & Limber, 1999) targets both elementary and middle school students and addresses the multifaceted nature of bullying and victimization. This program has been implemented in Norway, the southeastern United States, England, and Germany. Substantial reductions in bullying and victimization have been reported (more than 50%) as a result of this

Table 4. Components of child-centered, community-based MST model

- Low caseloads (i.e., 3–6 families per full-time therapist).
- Services are provided in the family's natural environment (home, school, and neighborhood).
- Services are time-limited; typically 3–5 months.
- Therapists are members of treatment teams.
- On-call status of at least one member of the team (i.e., 24 hours per day, 7 days per week).
- Appointments scheduled at the family's convenience.
- Daily contact via phone or face-to-face.

program. Specifically, several outcome studies have demonstrated the effectiveness and applicability of the Bullying Prevention Program (Hanewinkel & Knaack, 1997; Melton et al., 1998; Olweus, 1993; Olweus, 1994; Olweus & Limber, 1999; Whitney & Smith, 1993). Additionally, a "dosage-response" outcome has been reported, with a greater number of essential components of the program being linked to larger reductions in bully-victim problems (Olweus & Limber, 1999).

Table 5 presents an overview of the components included in the Bullying Prevention Program. The Bullying Prevention Program has as a goal to develop school and home environments that are characterized by (a) warmth and positive involvement by adults; (b) the setting of firm limits for unacceptable behavior; (c) predictable, non-hostile, non-physical consequences applied for unacceptable behaviors; and (d) adults as positive role models and authority figures (Olweus & Limber, 1999). The comprehensive nature of the Bullying Prevention Program emphasizes community and school involvement to establish an environment where bullying behavior is not tolerated at school, at home, and in the community.

In practice, a school psychologist can function as the on-site coordinator of the Bullying Prevention Program. Additionally, the school psychologist will be a member of the Bullying Prevention Coordinating Committee and can help coordinate aspects of the program (e.g., the school conference day) to increase awareness of bullying problems.

SUMMARY

The social realities of American youth indicate the dire need for health, mental health, educational, social, and other service agencies to work together in coordinated, systematic ways. The establishment of school-community partnership programs is inevitable for American schools—and youth—to thrive in the twenty-first century. School psychologists are in a pivotal position to promote, develop, and coordinate such programs. However, the task requires more than simply will and effort. In many cases it will require a reconceptualization of philosophies that school psychologists embrace. First, it requires school psychologists to think ecologically and systemically. That is, it calls on school psychologists to consider variables in a child's ecology (e.g., families, schools, neighborhoods, communities, agencies, peer groups) as potential clients, influences, and resources. Second, it requires school psychologists to assess their own role constructs in defining personal and professional responsibilities, activities, and priorities. Third, it requires school psychologists to communicate actively, visibly, and convincingly with other influential entities (e.g., school district and building administration, state legislatures) about the necessity of collaborative programs to support the needs of children and families, and to make efficient use of valuable resources. Finally, it requires school psychologists to become as prepared as possible (through additional education, training, and/or supervision) to grapple with the enormous complexity of school-community partnerships.

In this chapter we have attempted to articulate the foundations for and benefits of school-community partnerships, guidelines and steps for implementation, and example programs. Importantly, from an ecological perspective, the program developed and implemented in individual schools must be unique

Table 5. Community, school, and individual components of the bullying prevention program

Level	*Component*
Community	• Parent meetings (e.g., P. T. A.) • Volunteer study groups (parent circles) • Increase knowledge of bully/victim problems
Class	• Class rules against bullying • Regular class meetings with students • Meetings with parents of a class
Individual	• Serious talks with bullies and victims • Serious talks with parents of involved students • Teacher and parent involvement with targeted students

and responsive to the conditions within that community. Further, relational and not simply structural features of the program will be important to its overall success at meeting constituent needs. Given their training in data-based decision making, communication and collaboration, and program design and evaluation, school psychologists have a great deal to offer.

ANNOTATED BIBLIOGRAPHY

Howard, K. A., Flora, J., & Griffin, M. (1999). Violence-prevention programs in schools: State of the science and implications for future research. *Applied & Preventive Psychology, 8*, 197–215.

The authors review school-based violence prevention programs published from 1993 through 1997. Classroom-based curricula were components of every program reviewed and one third of the programs involved changing the school or other environments (i.e., home and community). It appears that elementary school interventions and programs that address change in the broader school environment are more successful in ameliorating violent behavior than junior high and high school interventions. The authors discuss the need to utilize comprehensive services that integrate community and home in violence-prevention programs. Additionally, the authors discuss the need for improved program evaluation: "There is little evidence to suggest the efficacy of any curriculum used alone or the superiority of any program over another" (p. 207). Thus, they note the need for evaluating the effectiveness of comprehensive intervention programs to help guide decision making.

McMahon, T. J., Ward, N. L., Pruett, M. K., Davidson, L., & Griffith, E. E. H. (2000). Building Full-Service Schools: Lessons learned in the development of interagency collaboratives. *Journal of Educational and Psychological Consultation, 11*, 65–92.

In this article, the authors begin by providing a brief yet useful summary of the history of school-community collaboration. This history is then expanded into a discussion of the concept of full-service schools. The main section of the article consists of a summary and discussion of 10 primary problems that have hampered the authors' efforts of establish full-service schools. This discussion provides helpful information to guide future efforts at establishing school-community collaboration within the context of full-service schools.

Nelson, G., Amio, J. L., Prilleltensky, I., & Nickels, P. (2000). Partnerships for implementing school and community prevention programs. *Journal of Educational and Psychological Consultation, 11*, 121–145.

These authors emphasize the importance of values and partnerships in planning and implementing community-based prevention approaches. They propose six steps that may serve as a guide for individuals as they plan and implement prevention programs in partnership with other stakeholders. Each step is expanded with examples from the authors' work in prevention initiatives.

U.S. Department of Education. (1995). *School-linked comprehensive services for children and families. What we know and what we need to know.* Washington, D.C.: Author.

This concise report summarizes the findings of a working conference focused on identifying a research and practice agenda on school-linked comprehensive services for children and families. The conference was based on the belief that schools cannot provide all the services that children and families need on their own. This group of researchers, service providers, family members, and representatives from federal agencies summarize major themes and current research, and provide direction for future research in this area.

24 Best Practices in Working With Culturally Diverse Children and Families

Samuel O. Ortiz and Dawn P. Flanagan
St. John's University

OVERVIEW

> On the whole...we are inadequately prepared to deal with cultural diversity.
>
> —Honigmann, 1963, p. 1

Separating oneself from culturally based ethnocentric viewpoints inculcated from birth by way of natural social interaction is a daunting task. The very essence of what an individual believes, thinks, and does is a product of unique background and developmental experiences that are most often shaped and determined primarily by culture. Even simply understanding the manner in which all humans are profoundly defined by culture and how it has led directly to the acquisition of almost every precious truth and deeply held conviction requires considerable effort and insight. Matsumoto (1994) notes, "sometimes we cannot separate ourselves from our own cultural backgrounds and biases to understand the behavior of others" (p. 6). Nevertheless, with respect to its impact on practice, school psychologists who work with students and families from diverse backgrounds must seek to understand the manner in which culture influences both their own view of others, and other's view of them.

If a reasonable set of guidelines for engaging in best practices with culturally diverse children and families is to be suggested, then the first and foremost principle must be this one: that any individual's own culture greatly affects the way they view the world and others, including people from both within and outside the culture. In working with students, families, teachers and administrators who come from cultural backgrounds and experiences quite different than those that typically comprise the U.S. mainstream, it is crucial to understand that these differences will affect the very things that school psychologists are often interested in, for example, learning, development, and behavior. It is equally important to recognize that there will be differences that are difficult to comprehend, appreciate, or accept and that such situations do not represent issues of right or wrong, good or bad, rational or irrational, but merely differences between people.

The task of delineating a framework for working with children and families from diverse cultural backgrounds hinges upon successful integration of a wide variety of practice-related topics—some of which have their own separate chapters (e.g., considering the role of culture, working with bilingual children, nondiscriminatory assessment, etc.). In order to work effectively with diversity in the schools, psychologists will need to develop competence in the skills and knowledge bases related to these areas and be able to integrate them in a manner that guides cross-cultural interactions. The issues and guidelines to be presented here are based largely on those presented in the preceding version of this chapter (Flanagan & Halsell Miranda, 1995). Unlike topics that can undergo considerable change in short periods (e.g., assessment), what was best practice over half a decade ago in working with diverse children and families still remains, for the most part, best practice today. Although it is acknowledged that what constitutes best practice in working with diverse children and families is not a topic area that changes considerably over time, it is nonetheless not an easy skill to acquire and maintain. Thus, one of the main reasons why there is a continued need for this information to be included in volumes such as this relates to the fact that school psychology training programs do not appear to provide sufficient direct supervision or instructional opportunities necessary to promote development of such competency (Geisinger & Carlson, 1998). The lack of culturally competent supervisors and trainers makes it difficult to incorporate such skills or knowledge into training regimens and school psychology curricula beyond the single course requirement needed to maintain accreditation. Consequently, the vast majority of school psychologists are sent into the nation's increasingly diverse schools wholly unprepared for interactions with diverse students, families, teachers, administrators, and fellow school psychologists. This chapter is intended to provide school psychologists with the information they will need and will seek, as diversity is met in the schools.

BASIC CONSIDERATIONS

Increasing Diversity

If the diversity of the U.S. population were constant and relatively unchanged, then it is likely that competency in working with culturally diverse children and families would remain a distant priority and largely unnecessary for those rare cultural encounters. But this is not the case. And although there is hardly a chapter on diversity issues that does not provide an abundance of demographic data to buttress the point, the statistics bear repeating here. By the year 2025, it is estimated that the U.S. population will increase to approximately 335 million people (U.S. Bureau of the Census, 1996). By itself, increased numbers of people are of little surprise. However, upon closer inspection of the data and the estimates upon which they are based, it is projected that 61% of the total growth over this period of time will come from Hispanic and Asian groups. By the year 2025, the Hispanic and Asian groups combined are projected to form almost a quarter of the entire population (24%) or about one in every four Americans. In addition, it is anticipated that other non-white groups will increase proportionately (Hispanic, Native American, African-Americans, etc.) whereas the percentage of Americans from European descent will decline. Growth patterns are predicted to be quite variable, with the greatest increases expected in California, Texas, and Florida as well as the southern and western portions of the United States (U.S. Bureau of the Census, 1996). Trends in the general population tend to reflect trends in the school population and it is clear that school psychologists will need to buttress their expertise in this area of practice.

The impact of increasing diversity is not limited to traditional definitions of the term that are based most commonly on cultural differences as a reflection of racial or ethnic differences. The concept and composition of families are transforming, creating new cultural systems based on dynamics apart from race or ethnicity. The percentage of traditional, nuclear families in the United States has been declining steadily while the percentage of single parent, step parent, grandparent, adoptive, foster, and same-sex parent families has been increasing (Copeland & White, 1991). Moreover, poverty has long been identified as a variable that meets most major definitions of culture and is an important influence in school performance (Hanson & Lynch, 1992). Similarly, people with disabilities represent a group whose experiences are becoming increasingly recognized as falling within the conceptual definitions of diversity and culture. Even diversity based on ethnic and racial differences has undergone significant changes. As people from different cultures continue to intermarry, the relatively "clear" delineation of race or ethnicity and the concomitant cultural idiosyncrasies that often accompany them will begin to disappear as they are blended into the mainstream and are subsequently expressed in new and unique ways (Frisby, 1998; Sandoval, 1998a).

The need to be comfortable and competent in dealing with children and families that come from nontraditional, non-white backgrounds will not lessen in the future. On the contrary, if the projections are accurate, such skill will become increasingly more important. School psychologists will need to recognize when their own values and beliefs impact their services to individuals whose backgrounds, experiences, and circumstances are distinctly different from those accustomed. Failure to appreciate the manner in which one's own culture influences interactions with individuals from a different culture can often lead to conflict, miscommunication, and misunderstanding, having tremendous impact on the nature and effectiveness of service delivery.

Definitions

The phrase "culturally diverse" differs slightly from the phrase "culturally different." Although there is much similarity between the two, the connotations of "diversity" are less severe than those from "different." The term "diversity" almost begs an inclusive, pluralistic perspective whereas "different" seems to set the stage for exclusion. Thus the phrase culturally diverse is preferable and will be used here. However, diversity does imply difference and it is acknowledged that the basis for establishing diversity rests on the premise of some type of difference among individuals or groups. The key, then, is the nature of those differences. Cultural diversity does not represent differences solely or strictly on the basis of racial or ethnic heritage. Although these factors are often associated with cultural differences, they are not in fact the same, as will be discussed. In general, cultural diversity refers to the unique background and experiences that have influenced, to the greatest degree, an individual's development (physical, emotional, cognitive, etc.). It is the existence of particular environmental elements and their unique influence on an individual or a group that comprises the essence of culture. School psychology in the United States has traditionally been practiced within the context of U.S. mainstream culture. Therefore, cultural diversity refers to any individual or group whose backgrounds and experiences differ significantly from that reflected by the U.S. mainstream. This definition helps to avoid the error of treating culturally diverse children and families as coming from a unitary, monolithic heritage and keeps the focus squarely on the fact that any two people from any single culture are similar only in that their respective backgrounds differ from that of the mainstream and perhaps from the school psychologist also. They may also differ significantly from each other. The following definitions are offered in an attempt to clarify the many dimensions along which cultural differences may exist.

CULTURE

It seems rather curious to have to point out that cultural diversity may exist as a function of cultural differences. What could be more obvious? Nevertheless, much confusion continues to surround the notion of culture probably because of its many connotations in the scientific literature and the popular vernacular. For example, culture may refer to the "characteristic patterns of living, customs, traditions, values, and attitudes that are associated with broad differences in intercontinental habitation or a society's level of technological sophistication" (Frisby, 1992, p. 533), as well as differences in language or religion. Those cultures that produce advances in technology and become industrialized are seen as "modern" whereas those that do not are seen as "primitive." Another definition of culture occurs when the term is included with a modifier that is intended to refer to a circumscribed group of individuals. The use of such phrases as "Deaf culture," "culture of poverty," "Western culture," "culture of the school," etc., are examples of culture defined in this manner (Frisby, 1998). Although the use of modifiers to specify particular groups of people may be valid in a general sense, it is important for school psychologists to understand that not every single individual from even the most circumscribed culture will display any or all of the features commonly associated with it. Individual differences do persist.

Perhaps the most common definition of culture revolves around the values, beliefs, and attitudes that are relatively unique to a given group of individuals and expressed in communal ways. A good example of this definition was put forth by Matsumoto (1994) who described this elusive concept "as the set of attitudes, values, beliefs and behaviors, shared by a group of people, communicated from one generation to the next via language or some other means of communication" (p. 4; see also Barnouw, 1985). Within the context of this definition, culture is seen as representing an element of consensus among a group of individuals regarding what is important and what will be maintained by the members and the children of the members of that group in particular. In this sense, culture is both a unique and shared experience that has idiosyncratic but predictable effects on virtually every aspect of development of its constituent members.

In sum, culture must not be viewed as "a rigidly prescribed set of behaviors or characteristics, but rather a framework through which actions are filtered or checked as individuals go about daily life"

(Hanson, 1992, p. 3). Individuals of the same cultural background will definitely share certain tendencies, but they will not necessarily behave in the same way. Other factors, including gender, age, socioeconomic status, area of residence, and level of education will also greatly affect behavior, beliefs, perceptions, attitudes, etc. (Hanson, 1992). Without question, the degree to which any individual follows the prescribed assemblage of cultural patterns under which they were raised varies considerably (Frisby, 1998; Hanson, 1992). When attempting to engage in best practices, school psychologists will need to remain well aware of the subtleties inherent in any definition of "culture" and avoid making any assumptions or generalizations that may be inappropriate or incorrect.

RACE AND ETHNICITY

Although these terms are often used interchangeably, they are quite distinct and each carries its own separate meaning with respect to culture. Ethnicity is much narrower in scope than race and reflects "a microcultural group or collectivity that shares a common history and culture, common values, behaviors, and other characteristics that cause members of the group to have a shared identity" (Banks & Banks, 1993, p. 357). The similarity between this definition of ethnicity and the previous definition of culture is noteworthy. On the whole, there is not much difference, but ethnicity tends to be even more confused with notions of race than culture. "Race" is simply a biological concept and refers to phenotypically distinct groups without reference to any other distinguishing qualities. Members of any given race may comprise a multitude of different ethnic and cultural groups. Race is much broader in scope than either culture or ethnicity and should not be equated with either. Rather, cultural traits represent the main attributes of an ethnic group whereas biological traits determine race (Banks & Banks, 1993). Understanding that neither race nor ethnicity automatically imply that an individual has had a cultural experience that is similar, let alone identical to any other member of the same racial or ethnic group, prevents the school psychologist from making attributions or generalizations that are unfair and untrue (Helms & Cook, 1999). This is particularly important in the assessment arena where interpretation is often based on notions of race or ethnicity without consideration of whether or not cultural experiences do in fact differ significantly from the mainstream. Good decision making in working with culturally diverse children and families requires a solid grasp of the distinctive characteristics of race and ethnicity as limited markers of culture.

MINORITY

The term "minority" has fallen out of favor as of late, perhaps in recognition of the fact that some previous minorities are now the "majority." In California for example, Hispanic children slightly outnumber Anglo children (California Department of Education, 1997). To call Hispanics a "minority" group is not only statistically inaccurate, it could be viewed as pejorative—a sort of semantic way of keeping diverse groups marginalized. The U.S. Census Bureau (1996) estimates that by the year 2050 the distribution of the population according to ethnic group in the United States will be such that no single group will represent a majority.

The term minority has historically carried implications regarding lack of privilege(s) or access to the mainstream, in particular the upper social strata. Members from minority groups have often been viewed as being disadvantaged (due to such factors as limited opportunity for educational or economic advancement) and treated unfavorably by the majority group (Helms & Cook, 1999). This notion has even crept into legislation for example, the Individuals with Disabilities Education Act (IDEA) contains the following wording: "the team may not identify a child as having a specific learning disability if the severe discrepancy between ability and achievement is primarily the result of…environmental, cultural or economic disadvantage" (§330.541). The idea of economic disadvantage seems appropriate, but there is nothing inherently disadvantaged about being culturally different. In considering issues of culture, it is perhaps best to avoid most conceptions of it as related to "minority" group status, except in one way. When minority status has resulted in unfavorable treatment or systematic oppression of members by the majority in power, the effects of being rendered underprivileged in this way may adversely affect the psychological well-being of the group's family life (Tseng & Hsu, 1991) and/or strengthen family or group bonds. But again, it is the experience of the oppression that is responsible for the influence on development, not the fact that an individual or family simply belongs to or identifies with any particular minority group.

SOCIOECONOMIC STATUS

The effects of socioeconomic status (SES) on the development of students and families, particularly within the school realm, have become so well known that it is not uncommon to refer to life under very low SES conditions as the "culture of poverty." Huang & Gibbs (1992) have demonstrated that social class has a profound impact on essentially every variable that influences an individual's physical and psychological growth and development including educational attainment, occupational aspirations, lifestyles, selection of friends, activities, and social roles. Experience (i.e., being raised) in one socioeconomic stratum versus another tends to delineate the range of opportunities, the kind of choices, and the degree of challenges that are available to individuals and their families (Huang & Gibbs, 1992). It can even affect the quality of the schools, buildings, and teachers.

Race or ethnicity should no longer be equated with social class or culture. Although the historical and socio-political history of the United States has created a rather high correlation between race and SES, they are not linked by necessity nor so easily circumscribed. Nevertheless, the U.S. mainstream continues to hold fast to notions that being white, heterosexual, non-disabled, and middle-class reflects high status whereas being anything else reflects lower status (Helms & Cook, 1999). Consequently, impressionable children may learn to devalue themselves and their own culture as they attempt to assimilate into the mainstream—often in vain because of racially based differences in physical features that belie Anglo or Caucasian heritage (Ortiz, 1999). School psychologists should therefore consider SES as an independent, albeit highly interrelated, cultural variable that influences development across a broad spectrum of individual functioning.

ACCULTURATION

Much like the preceding discussion on culture, ethnicity, and SES, the manner in which acculturation influences all forms of behavior in children and families rests upon issues of differential experiences, not merely differences. According to Salvia and Ysseldyke (1991) "acculturation is a matter of experiential background rather than of gender, skin color, race, or ethnic background" (p. 18). The standard by which acculturation is measured depends greatly on context and purpose. In the United States, where evaluations of student performance or behavior are conducted in the schools, the de facto standard is represented naturally, by comparisons with mainstream North American culture that implies English language proficiency and values reflecting predominantly Anglo or Western-European views. Thus, whenever the experiences of an individual, family, or group differ markedly from those of individuals who comprise the U.S. mainstream, expectations regarding functioning, performance, or behavior must be examined within the context of level of acculturation.

A number of authors have discussed ways of understanding acculturation in a variety of contexts. In his discussion of acculturation, Padilla (1980) describes a model that emphasizes cultural awareness, ethnic loyalty, and five dimensions of acculturative change (viz., language familiarity and usage, cultural heritage, ethnic pride and identity, inter-ethnic interaction, and inter-ethnic distance). Hoover and Collier (1985) described different sociocultural explanations for withdrawn, defensive, disorganized, and aggressive behaviors as exhibited by students that can be kept in mind when referring culturally and linguistically different children for special education. Sattler (1998) described factors affecting acculturation (e.g., history of migration experience), ways in which people deal with acculturation (e.g., marginality, assimilation), and suggestions for questions that can be posed during diagnostic interviews to help assess for a client's level of acculturation (e.g., inquiring about the language the client uses to speak with various family members and friends).

Atkinson, Morten, and Sue (1989) outlined five levels of acculturation that describe the manner in which diverse individuals or groups react to the dominant culture. The first level, conformity, is characterized by behavior that devalues cultural differences while at the same time praising the dominant culture. Dissonance, the second level, is defined primarily as a time of intra-psychic conflict where personal views regarding cultural differences shift between degrees of acceptance and rejection. Resistance and immersion form the third level of acculturation and is evident in patterns of general behavior that begin to show appreciation for cultural differences coupled with a certain degree of disdain for the majority culture. Introspection is the fourth level and is best described as a process whereby individuals attempt to explore the basis of their attitudes, in particular those that represent a liking of themselves and their inherent cultural differences. And last, synergetic articulation and awareness comprise the fifth level of acculturation wherein individuals come to appreciate both the cultural differences that exist, as well as particular aspects of the majority culture. Patterns of acculturation tend to be related to familial generations. The level at which an individual may fall on the acculturation spectrum is related to such issues as whether they represent the first among their family to come to the United States (but were not born here), versus their children who were born and raised in the United States (who are often bicultural and bilingual), to their grandchildren who were born and raised comfortably in the U.S. mainstream (and often speak English only).

Acculturation is not, however, a natural or invariant process. Many individuals or groups may deliberately choose to cling tightly to precisely those things that provide them with a sense of identity, even if it retains a measure of cultural difference. For some, acculturation is viewed as the process of assimilation whereby the native values, beliefs, and customs are gradually lost and replaced by the values, beliefs, and customs of the dominant culture (Ortiz, 1999). Consequently, different members of the same family may be at different points in terms of their level of acculturation. For example, highly impressionable young children may feel no loss in assuming new and culturally different social roles than their middle-aged parents. This difference in acculturation may even create acculturative stress (i.e., tension and disharmony within the family) and disrupt the family hierarchy. It is not uncommon in first-generation families to see the role of parents and children reverse, particularly when the child has acquired better English language proficiency than the parent and begins to act as liaison between the family and mainstream society in certain social contexts (Huang, 1989; Huang & Gibbs, 1992; Tseng & Hsu, 1991).

Knowledge regarding the level of acculturation for a family and the individuals who comprise the family provides an important perspective from which the school psychologist can develop plans for service delivery. Given the varying degrees of acculturation that may be experienced by culturally diverse children, families, and educators and its attendant impact on the attitudes, values, and beliefs held by them, the importance of assessing and evaluating acculturation levels carefully prior to engaging in any service delivery activities should not be overlooked.

Multicultural Training and Education

Despite the increasing diversity of the U.S. population, in particular within the schools, training and education toward cross-cultural competency development remains largely inadequate. With few exceptions, training programs that prepare individuals to work with diverse children and their families do not include large numbers of students from differing ethnic, cultural, and linguistic groups (Hanson, 1992). Multiculturalism, cross-cultural competency, and even bilingual assessment tend to enter the graduate school curriculum in the form of a single course, not always taught by individuals with significant professional training or education in these particular issues and not always including supervised experience with diverse children or families. Training and education directed toward development of competency in cultural skills and knowledge too often fall into a format perpetuated by books built upon the notion of "chapter cultures," that is, one chapter on African-Americans, one chapter on Native Americans, one chapter on Hispanics, one chapter on Asian Americans, etc. Such instruction is doomed to failure because true competency is unlikely to ever develop simply from reading a book (Frisby, 1998). Moreover, such courses rarely emphasize the importance of understanding one's own culture first before attempts are made to understand others (Lynch & Hanson, 1992). Consequently, as was discussed previously, failure to appreciate the manner in which one's own culture influences interactions with individuals from a different culture can often lead to difficulties in social interaction that negatively affect service delivery.

The solution to the question of engendering true cultural competence is rather simple, but the implementation is admittedly difficult. Many training programs have already seen the value of recruiting students from diverse backgrounds in order to both provide the school system with a source for psychologists with the desperately needed cultural knowledge bases and the opportunity for students to gain experiences in cross-cultural transactions during their graduate training. Other programs have already worked on expanding university curricula to include an emphasis on multicultural education (Banks, 1993; Hanson, 1992) but the efforts must move beyond notions of single courses and seek earnestly to provide experiences commensurate with the needs and expectations found in the course of actual practice (Geisinger & Carlson, 1998). In the meantime, school psychologists and other service providers have little choice but to attempt to develop cultural competency largely on their own—again, a major reason supporting the need for a chapter such as this. Books, articles, workshops, and other continuing education opportunities on issues related to cultural competence will form the bulk of the education and training school psychologists will likely receive once they have graduated from their programs. But whatever methods are employed to gain the skills and knowledge necessary for effective service delivery, school psychologists must develop and maintain respect for the inherent difference and value of other cultures as well as the notion that differences do not always imply disorders (Hanson, 1992).

BEST PRACTICES IN WORKING WITH CULTURALLY DIVERSE CHILDREN AND FAMILIES

Cultural Competence: Knowledge

SCHOOL CULTURE

Cultural competence is based partly on skills and partly on knowledge bases. School culture represents primarily a knowledge base. To understand the school as a culture unto itself, one only needs to ask whether the abbreviations IEP, IDEA, LD, ED, MR, ESL, etc., have any meaning to the lay person not employed in the schools. What seems to be perhaps the most public of our institutions is in reality a culture that is understood poorly by those outside of it (e.g., politicians, employees in other fields, and sadly, even parents) and only slightly better understood by those within it. Schools have rules, expectations, and norms for all sorts of functioning including behavior, language, attitudes, etc. There is little, if anything, that occurs in the schools that does not reflect the U.S. mainstream culture in one way or another. Samuda, Kong, Cummins, Pascual-Leone, and Lewis (1991) recognized that:

> We took for granted, also, the cultural orientation of the [White, Anglo-Saxon Protestant (WASP)] mainstream. The school was, in fact, a reflection of the middle class societal norms and teachers were frequently the purveyors of information couched in terms of a collective mindset that almost totally disregarded any kind of minority sociocultural perspective (p. vii).

The influence and the impact of the schools as a culture should not be minimized. Apart from the "book" learning that is taking place, much more is being learned in the school system. The very culture that gave rise to the public school system ensures that it teaches the values mirrored by society. Public school curricula are often based more on political and social agenda than on sound pedagogy (e.g., passage of Proposition 227, known as the "Unz initiative," in California in 1998 that greatly limited the implementation of primary language programs, or the continued efforts in various states to introduce "creationism" as an alternative scientific explanation or direct replacement for evolution as the origin of life on earth). What is taught in our schools is not there by mistake or chosen at random. It is chosen precisely and deliberately to espouse a particular point of view, a particular set of attitudes, beliefs, and ideology that mirrors the values held dearly by the mainstream culture.

The problem for the school psychologist is not that the dominant culture dictates the culture of the school. In fact, there have been significant advances in correcting some of the more egregious inequities perpetuated by culturally based ethnocentrism (e.g., the omission of historical and scientific contributions from non-white Americans, portrayals of Native Americans as uncivilized and obstacles to progress, views of slavery purely from political and economic viewpoints without regard to the toll on individual human beings and families, etc.). Rather, the problem for school psychologists lies in recognizing school as a culture and understanding the manner in which the system operates to inculcate a particular set of values in each and every student in attendance. As diverse children are imbued with these values, the effects can be broad and far reaching with potentially devastating consequences. Consider the following excerpt:

> Racism is often characterized, albeit facetiously, as an inherited disease—you get it from your parents. I guess I was lucky; I did-

> n't get it from mine. Like so many other unsuspecting children, I went out and got it from a more authoritative source, school.... I was infected with a far more insidious strain that taught me to hate my *own* people because they were different than what society said they should be...speaking Spanish simply wasn't allowed in school. Bilingual education was but a distant dream, and I was expected to learn English immediately upon entering kindergarten, never mind that my parents could barely speak it.... By second grade, my teacher placed me outside the classroom in a small group where I was teaching other Spanish speaking children how to read in English. I distinctly remember feeling superior to these children aspiring to be as proficient as I was in English.... It wasn't that anyone ever said anything to me overtly, and it wasn't that my parents didn't value their own culture or language. There just always seemed to be a clear, unspoken norm that English was *better* than Spanish and that being white was *better* than being brown. It wasn't based simply on being different; it was a question of value. White culture was superior to all other cultures, including mine (Ortiz, 1999, p.10, emphasis in original).

The possible effects of the culture of the school are indeed powerful ones. Best practices dictates that school psychologists fully understand the learning context that exists in each and every school and recognize that the context will differentially affect the learning and development of each and every student. Students whose backgrounds and cultural experiences are not consonant with the values taught in school may respond in ways that run counter to the typical educational expectations. Conversely, the very same children with diverse backgrounds and cultural experiences may respond in ways that are quite consistent with the public school system norms, as expressed in the quote above. In each case, the effects can be considerable (especially with respect to intra-familial relations or school-family relations) and it will be incumbent upon the school psychologist to carefully assess the forces that have shaped the individual and have served as the underlying influences on their development. When diverse children and their families are in need of educationally related services (e.g., counseling, assessment, consultation, behavior modification, instructional intervention, etc.) success will hinge in large part on the identification of the dynamics and similarities and differences in culture between the individual or family and the school.

FAMILY CULTURE

There is probably no greater arena in which the influence of culture operates more directly than within the immediate family. It could even be said that each family represents a unique culture in and of itself (Frisby, 1998). Development of a knowledge base that serves as the foundation for understanding the manner in which family systems work and how they represent cultural entities and transmit culture across generations, is crucial to the proper selection and design of educational services by school psychologists (Helms & Cook, 1999; Leigh, 1998). It is, however, well beyond the scope of this chapter to examine every aspect of families as cultural systems. Consequently, only a brief cross-cultural perspective of how family systems function will be presented and the reader is referred to Tseng and Hsu (1991) for a more comprehensive discussion.

"Family" is defined as "the basic sociocultural unit...the nest for the growth of an individual, the resource for social support, and the institution through which culture is transmitted" (Tseng & Hsu, 1991, p. 1). Although it is not the only method by which culture is passed on to new generations, the family group nevertheless plays a significant role in cultivating the growth, development, and psychological well-being of its children (Lewis, Beavers, Gossett, & Phillips, 1976). Families, as groups, are likely to come into contact with school psychologists or other service providers when a school-age member of the family has or is suspected of having a disability. Contact may occur informally (e.g., telephone contact, home visit) or more formally through some type of pre-referral process or actual referral for special education evaluation. Depending on the background, experiences, and familiarity with the school system, engagements with the family may be welcomed or they may be seen as threatening (Hanson, 1992). For example, families from many Hispanic and Latino backgrounds typically view the school system as entirely capable of handling any and all situations with their children. They generally seek not to interfere and when called upon by the school or school staff, even for innocuous or positive reasons, Hispanic families are likely to suspect that they are actually being summoned because of problems with their child. Naturally, they feel a great deal of embarrassment because the behavior of one member of the family is seen as a reflection of the family as a whole and thus they often arrive at meetings with a strong sense of shame and obsequiousness at having to intrude upon the teacher's or psychologist's turf (Dana, 1993). Similarly, the respect for educators within Hispanic families is quite large, and they are unlikely to provide much discussion or feedback, let alone critique, of recommendations offered for intervention services (e.g., special education services). School psychologists should be careful not to mistake the strong sense of respect accorded to all educators as a sign of passivity or disinterest in their child's education. Rather, the respect is so strong that it precludes doing anything that even gives the slightest appearance of disrespect and it carries an almost ironclad sense of trust. The educator is viewed as the professional and to question their decisions would be unthinkable (Dana, 1993).

School psychologists can provide culturally relevant services to families of different cultural backgrounds only if they understand the fundamental cultural aspects of family systems and function such as those just described. The particular aspects of family systems that may be most relevant to school psychologists would include variations related to marriage, residence, kinship, structure, power, and roles (Tseng & Hsu, 1991). Boyd-Franklin (1989) points out, for example, that with respect to family structure, African-Americans will likely have at least some regular involvement with extended family members. For this reason, she emphasizes the need for any service provider working with African-Americans to take the time to learn about the relationships that children and immediate family members have with extended family members. In similar fashion, Ruiz and Padilla (1979) suggest that it is important to remember that in addition to nuclear family relationships Latino family relationships include certain formalized kinship relations such as that of the godfather.

In summary, there are many different aspects of the family that need to be considered by the school psychologist from a cultural perspective. An understanding of the economic, political, ecological, and social conditions that play a role in shaping families' unique cultural patterns will aid in providing an individualized approach to service delivery, where intervention is tailored to the families' needs. Combined with knowledge regarding the school as a culture, a knowledge base regarding family as a culture will enable school psychologists to respond sensitively and effectively to families whose cultural practices differ from that of the mainstream or even their own.

Cultural Competence: Communication

In general, school psychologists who speak the same language(s) as the families they serve may have more effective interpersonal interactions than those who do not. The comfort level felt by parents or children who may not be fluent in English when given the opportunity to express themselves in their native language(s) is a substantial contributor to rapport (Helms & Cook, 1999). Effective communication is not, however, based solely on verbal or signed interchanges, but very often on nonverbal or gestural expression as well. The need for competence in the former (verbal or signed communication) can often be attained with the assistance of an interpreter/translator. Competence in the latter (nonverbal communication) will likely require application of a general knowledge base and perhaps even some cultural training from an individual familiar with the culture of the child or family to be served.

The amount of information that is communicated explicitly through verbal means versus that communicated through nonverbal means or contextual clues varies considerably from one culture to the next (Hall, 1976). In cultures where there is more use of high-context communication (e.g., Asian, Native-American, African-American, Latino) meaning is derived typically through shared experience, history, and implicit messages. In contrast, in cultures where the norm is based more on low-context communication (e.g., Anglo-European, American, Swiss, German, Scandinavian) meaning is derived primarily from direct, precise, and logical verbal interchanges (Dana, 1993). Communication norms within the culture of the school appear to be reflective of the low-context modality. Not surprisingly, misunderstandings between school psychologists and families may arise when the normal level of context typically used by each to communicate on an every day basis, differs significantly. Individuals from high-context cultures, for example, may perceive specific verbal directions, detailed examples, and extensive elaboration as insensitive and mechanistic whereas individuals from low-context cultures may feel uncomfortable with personal conversation, silence, obscure phrases, or unfamiliar gesturing. School psychologists should attempt to observe family communication patterns, as appropriate, or consult with an individual who may be familiar with the culture of the family in order to determine what level of context the family uses to communicate. This information will enable school psychologists to adjust their style of communication to match that of the families with whom they work, thereby increasing rapport and the likelihood of success with proposed interventions (Hanson, Lynch & Wayman, 1990; Lynch, 1992).

The use of an interpreter/translator can often assist considerably in managing communication between a school psychologist and a student or family. Interpreters/translators should be trained, however, specifically for the tasks they will be asked to perform. Finding an individual at the last minute and pulling him or her in to translate at a meeting shows lack of prior planning and could easily be seen as very disrespectful. Care should also be taken in matching the student's and the family's particular dialect. The expressions typically used by one cultural or ethnic group (e.g., Puerto Rican or Cuban) can differ markedly from the expressions used by another cultural or ethnic group (e.g., Mexican) even though each ostensibly speaks the same language, Spanish. The dialectical and regional variations may well create a sense of discomfort, awkwardness, and even conflict because the common usage of certain words and expressions from one ethnic group may be quite offensive to members from different ethnic groups. Beyond these considerations, school psychologists must ensure that interpreters/translators are used properly. The interpreter/translator should be seated in a manner that facilitates communication between the school psychologist or other professional and the parent or child. The interpreter/translator should not be used as a representative for the school or as an advocate for the parent and should be trained only to interpret and not offer opinions (often a strong temptation because the parent tends to build rapport with the interpreter). When speaking, the school psychologist should make it clear that they are speaking to the parent, not to the interpreter. Although it is awkward at first, the interpreter/translator should remain a background figure at all times, never the center of attention or the focus of the interaction. An interpreter should also be licensed, follow the professional Code of Ethics, and be compensated appropriately.

As stated previously, verbal communication is not the only method of communication in which school psychologists should seek to develop skills. Nonverbal communication and miscommunication can have dramatic effects on the nature of the relationship between a school psychologist and members of a family. For example, prolonged eye contact between individuals in Latino cultures is considered disrespectful, and any eye contact between a child and an adult is equally disrespectful. Similarly, eye contact between two strangers in some Asian cultures is regarded as shameful (Randall-David, 1989; cited in Lynch, 1992). Other nonverbal behaviors such as specific facial expressions, interpersonal distance (small for Hispanic and Asian cultures, larger for Anglo culture), type of physical contact permitted (e.g., a hand shake, hug, slap on the back), and gestural language are influenced greatly by culture and differ as a function of age, gender, religion, and personal preference as well as professional status and economic background. In the absence of concerted effort and sustained study, the average school psychologist is unlikely to learn all the culturally appropriate ways of communicating and behaving. However, with assistance, consultation, and informed readings, it is very possible for school psychologists to acquire enough skill and knowledge related to the more salient patterns of nonverbal communication within a given culture. Particularly important are the behaviors and gestures that show respect (e.g., bowing in Asian cultures, using titles and calling others by surnames only, no first names, in Hispanic cultures) (Dana, 1993; Lynch, 1992) and the often ritualized methods of greeting and dismissal.

Mastery of even a few skills related to showing respect or saying hello or goodbye in an appropriate manner can pay large dividends in the success of school psychology service delivery. Behaviors such as these tend to put the family at ease. For example, Hispanics tend to begin any function with polite talk about issues not directly related to the purpose for the meeting. To "get right down to business" would cause some discomfort for Hispanics as the more common method of attending to matters of import is to first spend some time in small talk about other issues (e.g., the family, health, work) and allow the conversation to turn naturally from personal things to the issue at hand. Engaging in such practices is not difficult, but may feel a little awkward to the school psychologist or other educator who feels time pressures bearing down on them. Engaging children and families successfully will require patience, effective listening skills, and a willingness to take the time necessary to establish mutual goals. Attempts to show deference, respect, and cordiality to diverse children and parents as well as diverse educators may not always be completely successful, but efforts and attempts to do so will likely be very much appreciated.

Despite the need to learn about some of the particulars of a culture and their manifestation in any given student or family, the most important component of effective communication is represented by the school psychologist's ability to view and appreciate the world from the family's perspective(s). Intervening effectively with students and families will come more from a genuine respect of their native values, beliefs, and attitudes than anything else that might be said or done, especially when their views run counter to beliefs that may be held so dearly. In such cases it must be remembered that school psychologists are not often in positions where they are designing interventions for themselves. Rather, the intervention is for others and they will only be successful in so far as they are culturally relevant to the children and families for whom they are intended.

Cultural Competence: Skills

Cultural competence is not a discrete skill or set of facts. To view cultural competence in such a light would be a great disservice. As mentioned at the outset, cultural competence represents the integration of a wide variety of knowledge bases and specific competencies that encompass many aspects of work with diverse children and families. Cultural self-awareness represents the first step to developing skill and competency in cross-cultural service delivery (Helms & Cook, 1999; Leigh, 1998; Lynch, 1992). This was recognized in the introduction to this chapter where the ability to serve diverse children and families was stated to come from an appreciation of the impact of one's own culture(s) on perceptions of self and others from both within and outside the culture. School psychologists should strive to develop keen insight into how one's own values, beliefs, experiences, attitudes, languages, and customs have been molded by culture. Shweder (1986) put it succinctly, "the best way to get inside yourself is to go outside yourself, and as any good ethnographic knows, if you cannot find yourself in the other, you are not going to find yourself at all" (p. 38).

SELF-AWARENESS

The need to recognize school systems as cultural entities and the values that they infuse into the curriculum were discussed previously. The basis of the values being indoctrinated by society into children in the schools, and in children and families outside the school (e.g., through the media), comes from mainstream U.S. culture. Typical North American values are derived primarily from Western European influence and tend to emphasize individualism, independence, autonomy, interpersonal competition, mastery, equality, punctuality, materialism, progress, and a future orientation. Moreover, there are elements of our culture that value interactions that are more informal as opposed to formal, that display a high regard for individual achievement, and that foster pride in direct and assertive interactional communication styles (Helms & Cook, 1999; Leigh, 1998). School psychologists who understand the extent to which they identify with each of these values will be in a better position to determine how the values that they adhere to most strongly affect their practice (Leigh, 1998; Lynch, 1992). Moreover, they will be more likely to appreciate the influence that mainstream culture is having on the development and functioning of culturally diverse students, families, and colleagues.

Self-awareness involves recognition of differences in one's own world view from that of others. For example, school psychologists who tend to value independence and autonomy in young children or who believe in promoting the attainment of developmental milestones and correcting slight deviations from the norm, may have considerable difficulty understanding why some Native-American and Hispanic-American parents seem to have a relaxed attitude toward their children's achievement of self-reliance (Huang & Gibbs, 1992). Similarly, school psychologists who tend to value individual achievement and interpersonal competition may find themselves at odds with families who come from a cultural background that values interpersonal affiliation, cooperation, and reciprocity (e.g., Hispanic-American families). And finally, school psychologists who tend to believe that the source of a child's disability lies in physical phenomena rather than spiritual factors will need to work through the dissonance that may result from interactions with parents who are committed to spiritual rather than medical treatments (e.g., some Southeast Asian groups) or some fundamental forms of "mainstream" religion (e.g., snake holding, immersion in water) (Chan, 1986; Harry, 1992). Clearly, the extent to which a school psychologist's own cultural values differ from those of other cultures as well as the extent to which adhering strictly to those values affects service delivery to diverse children and families is a necessary requirement for engaging in best practices. Honest and genuine cultural self-awareness and appraisal provides the foundation from which the cultural elements of others can be best understood and brought to bear on improving personal and working relationships with diverse students and families.

DATA GATHERING

School psychologists spend a significant amount of time in activities that are designed specifically to collect information that serves a variety of applied purposes including assessment, evaluation, consultation, and counseling. In all of these components of service delivery, specific information about cultural elements relevant to the purpose for collection helps significantly in being able to understand the values, beliefs, and behaviors operating to define functioning or behavior of any kind. Not only does such knowledge affect the manner in which any collected data might be interpreted, but it also influences the very nature of the data that are sought and collected in the first place and how these data are later defined and used. For example, when a school psychologist hypothesizes that poor academic work may be the result of a disability, all interview questions, all observations of behavior and performance, all meaning ascribed to information contained in school records, and all data from testing may be interpreted within the context of providing support, not refutation, of the presumption of dysfunction. Cultural factors that may have significant relevance to and influence over the precise meaning of all of the data are dismissed, ignored, or left uncollected because the presumption steered data gathering efforts in a particular manner that did not include or place much importance on such factors (Sandoval, 1998b). In order to avoid errors in practice of this nature, school psychologists should adhere to gathering culturally-relevant information in line with the following principles:

1. *Establish rapport and build trust.* Use the knowledge bases regarding displays of respect, and appropriate greeting behavior and exiting behavior. Help the family to feel at ease, respected, and provide the opportunity for the family members to fully participate and contribute to the process of service delivery. Use interpreters/translators as necessary but make sure they are appropriately trained and consult with individuals who are familiar with the culture and languages relevant to the purposes of service delivery.

2. *Identify the presenting problem.* School psychologists should listen carefully to the family's perception of any suspected problem and attempt to understand it from their perspective. They may feel there is no problem at all. It is also necessary to determine the family's past efforts to resolve the problem and to elicit their present understanding of new intervention strategies and goals. Once these issues have been clarified, the school psychologist will be in a much better position to negotiate intervention strategies.

3. *Learn the family system.* The structure of the family system must be assessed and determined to the maximum extent possible. Particularly important to evaluate are the areas related to family composition, family members' roles and responsibilities, family's interactional patterns, family's support system, family's childrearing practices, and the family's beliefs about the student's suspected handicapping condition and its source. Knowledge of the relevant aspects of the structure of the family system provides the basis for interventions that are appropriate and individually tailored to the particular needs and resources of the family.

SUMMARY

This chapter provided school psychologists with both the background information and the methods necessary from which to begin to develop greater competency and skill in providing services to diverse children and families. Several key concepts were defined in an attempt to aid school psychologists in determining the important dimensions along which families differ, including culture, ethnicity, race, socioeconomic status, and level of acculturation. In addition, a framework for understanding how family systems function was presented from a cross-cultural perspective and strategies for developing cross-cultural competence were offered. The final section contained in this chapter included a discussion on best practices that centered around three areas of competence including knowledge, communication, and skills as well as practical guidelines for gathering culturally relevant information about families.

Until recently, little attention has been given to developing cross-cultural competence and understanding the manner in which cultural differences affect school psychology service delivery. Achieving cultural competence is an intentional and challenging process that requires individuals to take risks, lower their defenses, and set aside their own beliefs in an attempt to appreciate another's point of view. It is expected and not uncommon for individuals who have just begun to foster development of cultural competence to have some encounters with diverse students or families that have proven to be uncomfortable or less than successful. The rapidly changing demographics of the U.S. population with respect to diversity leaves many school psychologists faced with the challenge of providing services to culturally diverse children and their families for which they may not be well prepared. The absence of substantial and systematic training, education, and supervision toward the development of cultural competence creates a strong need for relevant information and useful strategies applicable to service delivery to diverse children and families. The information and specific strategies offered here are meant to serve as a readily accessible compendium for school psychologists searching for assistance. Despite the existence of a chapter of this type, it must be recognized that acquiring cultural competency and skills is a lifelong process. Developing cultural competence does not happen overnight and one cannot expect to know everything there is to know about every culture. However, through an open mind and a willingness to implement new ideas, acquisition of specific strategies will enable school psychologists to work effectively and sensitively with culturally different families as well as enable families to feel comfortable about their interactions with service providers. Learning about another culture and developing the skills necessary to communicate effectively with its members is a process that begins with the very first family with whom school psychologists work and with deliberate effort improves steadily over time as cross-cultural interactions and experiences increase.

ANNOTATED BIBLIOGRAPHY

Leigh, J. W. (1998). *Communicating for cultural competence*. Boston: Allyn & Bacon.

This book is predominantly geared toward social work practice. Nevertheless, both the information and the strategies offered for developing cultural competence are equally applicable to the school psychologist. There are excellent exercises and materials within that make it a very useful tool for advancing one's own competency.

Lynch, E. W., & Hanson, M. J. (Eds.). (1992). *Developing cross-cultural competence: A guide for working with young children and their families*. Baltimore: Brookes.

Part I introduces issues regarding provision of services to diverse families with a focus on developing intercultural effectiveness. Part II describes the history, values, and beliefs of the major cultural and ethnic groups in the United States. Part III offers suggestions and recommendations for working with diverse families.

Sandoval, J., Frisby, C. L., Geisinger, K. F., Scheuneman, J. D., & Grenier, J. R. (Eds.). (1998). *Test interpretation and diversity: Achieving equity in assessment*. Washington, DC: American Psychological Association.

This volume is more in line with assessment issues; however, the discussions surrounding issues of cultural and linguistic competence are excellent. The writing is clear and cuts across topic areas in school psychology to provide a framework for working with diversity that is practical and up to date.

Tseng, W. S., & Hsu, J. (1991). *Culture and family: Problems and therapy*. New York: Haworth.

This book offers a comprehensive overview of family systems from a cross-cultural perspective. Critical issues regarding family development, family subsystems, and family adjustment are discussed and cultural considerations in family assessment and therapy are presented.

Best Practices in Increasing Cross-Cultural Competence

Antoinette Halsell Miranda
The Ohio State University

"Diversity is not a choice, but our responses to it certainly are."

(Howard, 1999)

OVERVIEW

The rapidly changing demographics of the United States have increased the need for establishing a knowledge base in the area of cultural diversity. In 1998, among students enrolled in elementary and high school 63.8% were non-Hispanic white, 16.1% were non-Hispanic black, 4.1% were non-Hispanic Asian and Pacific Islander, and 14.3% were Hispanic (U.S. Census Bureau, 1998). About 19.8% (9.5 million) of elementary and high school students have at least one foreign-born parent, and 4.9% (2.4 million) of elementary and high school students are themselves foreign born. The vast majority of immigrants entering the United States are from nations in Asia and Latin America . In 1999, whites were 71.9% of the U.S. population; however, by the year 2025 those numbers will decline to 62.4% of the U.S. population. Those Hispanics living in the United States are projected to outnumber African Americans early in the twenty-first century. The United States Census Bureau (1998) projects that by 2025 Hispanics will be 18% of the U.S. population. Over the next 25 years, people of color are projected to increase in all parts of the country but especially in the south, southwest, and west. By 2025, people of color are expected to account for more than 50% of the population in four states (Hawaii, California, New Mexico, and Texas) and the District of Columbia. (U.S. Census Bureau, 1998).

Because psychologists are increasingly encountering people who are culturally different than they are, Sue, Bingham, Porche-Burke, & Vasquez (1999) felt it necessary to discuss the need for the profession of psychology to address issues of race, culture, and ethnicity. They advocate for a multicultural psychology to address the challenging issues of diversity. Multicultural psychology requires revolutionary change and can best occur through the implementation of cultural competence of all aspects of the profession (Sue et al., 1999). Many in the discipline of school psychology have also recognized this need, and as a result numerous researchers have suggested that school psychologists ought to address this growing need to have culturally competent professionals (Gopaul-McNicol 1997; Ramirez, Lepage, Kratochwill, & Duffy, 1998; Rogers, Ponterotto, Conoley, & Wiese, 1992).

Unfortunately, while our school age population is becoming increasingly diverse, our school psychology profession for the most part remains predominately Caucasian. The latest demographics of the profession found that only 5.5% of school psychologists in the field are people of color (Curtis, Hunley, Walker, & Baker, 1999). It is expected that limited representation of underrepresented groups will continue to confront the field of school psychology. Because of this increasing disparity between students and practitioners, it is essential that training programs provide students in school psychology with the skills to respond effectively to diverse populations. (Curtis et al., 1999.).

Over the past two decades, the two major organizations that represent school psychologists, the

American Psychological Association (APA) and the National Association of School Psychologists (NASP), have attempted to address this issue in a variety of ways. Diversity issues are addressed in the standards of both professional organizations (American Psychological Association, 1993; National Association of School Psychologists, 1995), and they both have standing committees dedicated to addressing the issue. APA has also developed Guidelines for Providers of Psychological Services to Ethnic, Linguistic, and Culturally Diverse Populations (American Psychological Association, 1993) and has approved resolutions that address issues of diversity in graduate education in psychology (American Psychological Association, 1987). NASP has established a minority scholarship fund.

Historically, despite the growing recognition that school psychologists need to acquire the knowledge and skills to be able to work with culturally diverse populations, diversity has not been reflected in school psychology literature. In an investigation of multicultural themes in school psychology literature over a decade and a half (1975–1990), Rogers Weise (1992) found that only 9% of the total articles in the three major journals (*Psychology in the Schools*, *Journal of School Psychology*, and *School Psychology Review*) reflected multicultural content. With respect to the focus of the research, 77% of empirical research was on assessment issues and the school psychologist's role as psychoeducational evaluator. In contrast, only 3% of the articles dealt with the impact of issues of culture and ethnicity and the role of consultant and counselor, and no studies dealt with the impact on other roles such as supervisor and program coordinator. A recent study (1990–1999) has found that the multicultural content of the four major school psychology journals has increased slightly from 9% to 10.8% (Halsell Miranda, & Gutter,, 2001). Six journal issues had diversity as a special topic, and these articles accounted for 25% of the total multicultural articles.

In school psychology, our cultural diversity literature has primarily focused on assessment practices particularly as it relates to assessment bias (Barnett et al., 1995). What we do goes far beyond assessment. To develop the essential knowledge and skills to respond to the increasingly diverse population, it is imperative that the field of school psychology increases its literature base in the area of diversity, particularly as it relates to the potential influence of cultural factors within work settings.

Several researchers have also expressed the need for more diversity training (Curtis et al., 1999; Ramirez et al., 1998; Rogers, Ponterotto, Conoley, & Weise, 1992). The challenge is how to train students to develop the skills they need to effectively work with diverse populations. How do we train school psychology students in the area of diversity so that they (a) are able to understand differences across cultures as well as differences within cultures, (b) are able to understand that there are more differences within groups than between groups, (c) understand the difference between stereotypes and sociotypes, and, most important, (d) become comfortable in discussing issues of diversity in their delivery of school psychology services?

It is a challenge that trainers of school psychologists need to examine. So many programs do not, or only minimally, infuse the content into their courses, and trainees often have limited access to minorities during their field experiences (Rogers et al., 1992.). Thus, many practicing school psychologists may not have been trained to work with children who are culturally different than they are. The purpose of this chapter is to provide a framework for school psychologists to recognize how culture can potentially influence the practice of school psychology and how to effectively work with children from a cultural perspective.

BASIC CONSIDERATIONS

There are important key concepts in working with culturally diverse populations that will help to illustrate the complexity of our diverse student population and to view students from a multidimensional perspective rather than a one-dimensional perspective.

Culture. "The ideations, symbols, behaviors, values, and beliefs that are shared by a human group" (Banks & McGee Banks, 1993, p. 357). Culture can be thought of as a blueprint, which guides people through everyday life. For some groups, culture is the group's program for survival and adaptation to environment (Banks & McGee Banks, 1993). Culture is learned, shared, an adaptation, and a dynamic system that changes continuously (Gollnick & Chinn, 1990).

Cultural group labels are used to identify groups of individuals that share many aspects of behavior and values. This is called a group's identity. This identity helps to create bonds between individual members of the group and to continue the group socialization process with children (Lynch & Hanson, 1998). However, it is critically important for practitioners to understand that "these labels only point to tendencies of members of that group" (p.17). The individual differences and within-group variations of cultural groups must be acknowledged. The challenge for practitioners is to learn how to use central or common tendencies as cues to understanding diverse populations instead of using those tendencies as blanket stereotypes that universally apply to everyone in that group.

Race. "A social construct that artificially divides people into distinct groups based on characteristics such as physical appearance (particularly color), ancestral heritage, cultural affiliation, cultural history, ethnic classification and the social, economic, and political needs of a society at a given period of time" (Wijeyesinghe et al., 1997, p. 88). Race is often viewed as a socially constructed concept. Unfortunately, we are a race-conscious society, and the concept of race persists and remains a primary basis for categorization in the United States.

Ethnicity. "A social construct which divides people into smaller social groups based on characteristics such as a shared sense of group membership, values, behavioral patterns, language, political and economic interests, history and ancestral geographical base" (Wijeyesinghe et al., 1997, p. 88). Ethnicity is often used interchangeably with race. While they are not the same, they often overlap.

Racial and Ethnic Identity. "An individual's awareness and experience of being a member of a racial and ethnic group; the racial and ethnic categories that an individual chooses to describe himself or herself based on such factors as biological heritage, physical appearance, cultural affiliation, early socialization, and personal experience" (Wijeyesinghe et al., 1997, p. 88). Ethnic identity can provide a framework through which growing children can view themselves and can provide meaning to the child's subjective experiences, structure to interpersonal relationships, and behaviors and activities (Gibbs & Huang, 1998).

Racism. "A belief that human groups can be validly grouped according to their biological traits and that these identifiable groups inherit certain mental, personality, and cultural characteristics that determine their behavior" (Banks & McGhee Banks, 1993, p. 359). The real crux of racism is that it goes beyond a belief. Racism is practiced by one group over another group. Usually because of larger size, one group has the power to enforce laws and norms based on those beliefs to oppress another, usually smaller and more fragile, group. Racism usually operates on three levels: individual, institutional, and cultural. At the *individual level*, it is the beliefs, attitudes, and actions of an individual that support or perpetuate racism. The individual generally has the belief that his or her race is superior to another. Individual racism can occur at both an unconscious and conscious level. *Institutional racism* "consists of those established laws, customs, and practices which systematically reflect and produce racial inequalities in American society" (Jones as cited in Bennet, 1995). It should be noted that those executing these practices might not have racist intentions. Institutional racism may be hard to detect, because it may be more covert. *Cultural racism* occurs when one (powerful) group imposes its cultural heritage upon other (less powerful) groups thus destroying the culture of the less powerful group (Bennett, 1995). Racism is a complex issue that includes attitudes, power, and an ideology of ethnocentrism or cultural superiority.

Prejudice. Rigid and unfavorable attitudes directed toward a group that are formed regardless of facts. A prejudiced individual responds to members of a particular group based on preconceptions, ignoring behavior or characteristics that may be inconsistent with biases (Banks, 1997).

Social Class. A dimension that describes and defines a person's world by ascribing a specific position and value to based on their socioeconomic status (SES) (Gibbs & Huang, 1998). Social class is a particularly important concept because it intersects with culture, race, and ethnicity, with all three becoming an interacting dimension of the child's life experience. "The family's SES will largely determine the child's social environment, lifestyle, level of education, and occupational aspirations" (p. 11). Often social class is a more important determinant than race or ethnicity.

What we sometimes consider "culture" is in fact a result of poverty.

Minority Group. "A group of people who because of physical and cultural characteristics, are singled out from others in the society in which they live for differential and unequal treatment, and who therefore regard themselves as objects of collective discrimination" (Wirth, 1945, p. 347).

Assimilation. "The process by which an individual or group acquires the culture traits of a different ethnic or cultural group" (Banks, 1997, p.72). Gordon (1964) described the assimilation process as developing through stages, with each stage representing a degree of assimilation. Cultural or behavioral assimilation is considered the first stage, and it is here that the cultural groups will have direct contact with the dominant group, which leads to eventual changes in the groups' original cultural patterns. Structural assimilation occurs when two groups share primary-group relationships, such as membership in social clubs (Gollnick & Chinn, 1990). The dominant group determines the degree of structural assimilation. "If the assimilation process is effective, it leads to the disappearance of a cultural group that is distinct from the dominant culture" (Gollnick & Chinn, 1990, p. 19). Some consider the true test of assimilation for cultural groups as the absence of prejudice, discrimination, and value and power conflict. For ethnic minorities in the United States, assimilation, by this test, has not happened.

Acculturation. A process by which the views and behaviors of one group are modified as a result of contact with another culture (Gopaul-McNicol & Thomas-Presswood, 1998). Banks (1997) described acculturation as occurring when two cultural groups exchange cultural elements, such as food, dress, and music. Unlike assimilation, groups that go through acculturation often maintain elements of their own culture. Acculturation is influenced by immigration status, exposure to other cultural groups, socioeconomic status, and educational level.

Training Issues

Understanding the key concepts of diversity is important because they are frequently used in discussions of diversity. In addition, the concepts are often used interchangeably (such as "ethnicity" and "race"). Thus, the real meaning may get lost. Training in the area of cultural diversity is not simply learning about racial, cultural, and ethnic groups, as was the major focus of early cultural diversity courses. In fact, this type of training often teaches broad characteristics of groups viewed as absolute truth, which only serves to stereotype. Cultural diversity training should help students understand how issues of race, class, and ethnicity are interrelated with politics, economics, and power. Issues of diversity are complex issues and should not be relegated to one course. Understanding diversity issues from a historical, sociological, as well as psychological perspective is important. Trainers as well as practitioners must not be fearful to address and confront the most difficult and often taboo topics, such as race, oppression, and social justice. Jacobs (1999) states that "race has become so toxic a topic in America that many of us are afraid to even touch it, at least in public, without some kind of industrial-strength protection" (p. 3). In order to make progress, we need to have open and honest discussions that will facilitate a better understanding about the issues and diminish our tendency to resort to understanding groups through stereotypes. A complete level of understanding takes time and commitment and a different worldview. "The ability to differentiate the general from the specific, the universal from the unique, is critical to effective work with children of all cultures and backgrounds (Gibbs & Huang, 1998, p.362).

BEST PRACTICES

Cross-Cultural Competence

Many researchers in the field of cultural diversity discuss the development of cross-cultural competence (Gopaul-McNicol, 1997; Pope-Davis & Dings, 1995); that is, the development of skills that enable the professional to be "competent, sensitive, and knowledgeable of the critical factors related to issues of cultural diversity to best serve minority students" (Gopaul-McNicol, 1997, p.17). Lynch and Hanson (1998) describe cross-cultural competence as "the ability to think, feel, and act in ways that acknowledge, respect, and build upon ethnic, sociocultural, and linguistic diversity" (p.50). The process of developing cross-cultural competence has been described by many, usually with some element of variation. However, all of those processes have in common three elements: developing a personal awareness, developing a knowledge of other cultures, and applying that knowledge.

DEVELOPING A PERSONAL AWARENESS

In order to be able to work effectively with another cultural group, people must first understand their own cultural heritage. Everyone has a culture. Members of the majority culture are often unaware of just how their culture has influenced their values and beliefs. Many have never really examined where they came from and how they got to where they are.

How we view the world is influenced by our experiences. Lynch and Hanson (1998) advocate searching for roots through an exploration of such things as family's origin, time of immigration, reason for immigration, and family's settlement in the United States. Other potential influences are languages spoken, religion, politics, economics, and socioeconomic status. This goes beyond simply doing a genealogy. A significant aspect of this self-examination is an analysis of the socialization process during development. Exploring our own cultural heritage allows us to develop an understanding of how we have been socialized to view the world.

The socialization process is often influenced by the family's values, beliefs, behaviors, and customs that are associated with cultural norms. Part of that exploration also includes a critical look at how we were socialized to deal with people different than ourselves as well as our own experiences with race. While it may be painful for some, it enables others to confront potential biases and prejudices that may have been a part of their socialization process. Knowing you have a bias gives you an indication, or warning, of where those biases may intersect with your professional, and personal, behavior. This self-awareness creates a foundation that you can use to learn, objectively, about other cultures and lifestyles without conscious prejudicial constraints. However, be aware that your unconscious bias must be dealt with, too.

DEVELOPING KNOWLEDGE OF OTHER CULTURES

There are a number of ways to develop a knowledge base about other cultures. Lynch and Hanson (1998) suggest that the four most effective ways are reading books, interacting with people from diverse cultures who can act as cultural mediators, participating in the daily life of another culture, and learning the language of the culture. Reading is probably the easiest and least threatening, though it should not be the only means by which information is gathered. Literature can provide diverse views of culture. Reading and understanding the historical context of other cultures can put many of the issues in perspective. Reading provides a broader perspective of cultures while helping the practitioner see the continuum of culture.

Interacting with people from diverse cultures who can act as cultural mediators is particularly helpful in learning more about their beliefs, values, and practices. Cultural mediators help bring what you have read to life and provide opportunities to ask questions about what you have read and/or experienced. Nothing is more powerful than hearing the experiences from somebody who lives it. Nuances of culture and cultural practices can be learned through cultural mediators as well. One must remember, however, that the cultural mediator is also sharing his or her culture through his or her personal lens.

Participating in the daily life of another culture or carrying out a cultural immersion experience is an excellent way to increase cross-cultural understanding. Participation in the life of another culture allows a symbolic and persuasive awareness and understanding. For many, this activity will be a challenge, but part of developing cross-cultural competence is taking risks.

Learning the language of another culture takes one of the strongest commitments, and probably is the most difficult to achieve, particularly for adults. Language is considered important because so much of culture is reflected in language.

APPLYING THE KNOWLEDGE

Considering culture in the practice of school psychology provides the practitioner with the opportunity to address issues of diversity in an effective and systematic manner with the goal of providing optimal services to a culturally diverse population. Having a personal awareness and a knowledge base of cultures are essential prerequisites to practicing school psychology cross-culturally.

Becoming cross-culturally competent requires taking emotional risks. It is not always uncomplicated and painless when discussing these issues and confronting them. It is important to listen to people with very different ideas and experiences. This does not necessarily mean you have to agree with everything you hear. Different perspectives are just that: different ideas, different ways of looking at the same thing. It may require you to learn to relook, reconceptualize, reexamine, and rethink, and it is the beginning of practicing school psychology in a cross-culturally competent manner. In applying the knowledge and understanding concepts such as identity development and dual socialization may be helpful in your attempt to determine whether culture is a factor that is affecting the problem situation.

Identity Development. Tatum (1997) states "identity development as integrating one's past, present, and future into a cohesive, unified sense of self is a complex task that begins in adolescence and continues for a lifetime" (p.20). Culture shapes identity. "Identity is influenced by a culture's language, social structure, rituals, and taboos in terms of how one views situations and events, particularly outside of their culture" (Baruth & Manning, 1999, p. 30). Identity development is a continuing process, but significant development occurs during adolescence and can include religious beliefs, values and preferences, gender roles, career goals, and ethnic identities. "While all adolescents struggle with identity issues, not all adolescents think about themselves in racial terms" (Tatum, 1997, p, 53). School psychologists working in multicultural settings need to understand both culture and development. "Understanding one entity without understanding the other limits the [school psychologist's] ability to intervene, especially with [students] of differing cultural backgrounds." (Baruth & Manning, 1999, p. 31).

Research has documented the relevance of racial and ethnic identity theory (Cross, 1995; Helms, 1995). The identity models tend to be stage models, which have the "advantage of considering race-related adjustment as a dynamic process that can be modified" (Helms, 1995, p. 182). School psychologists working with middle and high school students may find identity development to be an important variable to consider. Phinney and Tarver (1988) studied black and white eighth graders from an integrated urban junior high school who were on the search for identity. They found that among the 48 participants, more than a third were considering the effects of ethnicity on their future. Not only were they considering it, but also discussing it with family and friends and learning more about their ethnic group. While both groups were beginning to think about ethnic identity, the results suggested that blacks were more engaged in an active search. Tatum's (1997) research on black youth in predominantly white communities yielded results consistent with Phinney and Tarver's findings. She believes environmental cues that trigger an examination of racial identity become particularly evident in middle school.

A phenomenon sometimes seen with African-American youth in the middle and high school years is "oppositional identity." Oppositional identity has been described as an "oppositional stance [that] both protects one's identity from the psychological assault of racism and keeps the dominant group at a distance" (Tatum, 1997, p. 60).

> Sometimes the emergence of an oppositional identity can be quite dramatic, as the young person tries on a new persona almost overnight. At the end of one school year, race may not have appeared to be significant, but often some encounter takes place over the summer and the young person returns to school much more aware of his or her Blackness and ready to make sure that the rest of the world is aware of it, too. There is a certain "in your face" quality that these adolescents can take on, which their teachers often experience as threatening (Tatum, 1997, pp. 61–62).

Often these students, as a positive coping strategy, will only affiliate with others from their same racial group as a source of support. The problem with oppositional identity from Tatum's point of view is that these adolescents are operating from a limited definition of what it means to be black, based largely on cultural stereotypes.

Thus, the consideration of racial and/or ethnic identity of students can be used as a tool for helping the practitioner understand the issues the student may be facing not only personally but also academically.

Dual Socialization. As was discussed before, culture occurs on a continuum and is influenced by the process of dual socialization. Dual socialization is "the process of bicultural socialization through which minority parents teach their children how to function in two distinct sociocultural environments" (DeAnda cited in Gibbs & Huang, 1998, p. 12). This important concept helps explain some of the variability within cultural groups. DeAnda believes six factors influence the outcome of the process of dual socialization:

> (1) the degree of overlap or commonality between the two cultures with regard to norms, values, perceptions, and beliefs; (2) the availability of cultural translators, mediators, and models; (3) the amount and type of corrective feedback provided by each culture regarding a person's behaviors in the specific culture; (4) the congruence of conceptual and problem-solving styles of the minority individual with those of the mainstream culture; (5) the individual's degree of bilingualism; and (6) the degree of similarity in physical appearance to the mainstream culture (Gibbs & Huang, p. 12).

Individuals who are able to negotiate two cultures successfully are said to be bicultural. Sue and Sue (1977) identified three variables to assess in students of color in determining the impact or influence of culture. These also influence the socialization process and can affect the continuum of biculturalism. The variables are culture-bound, language-bound, and class-bound. *Culture-bound variables* include knowledge of the cultural background, attitudes, and norms. *Language-bound variables* are knowledge of the family's first language, immigration history, and acculturation level of the family. *Class-bound variables* include the family's socioeconomic status and its impact, community experiences, and the family's aspirations.

Ecological Perspective

The use of an ecological perspective as proposed by Bronfenbrenner (1979) fits nicely with the idea of viewing a child in a cultural context. An ecological perspective views the child as an active participant in a system that is connected at all levels. Deficits are not seen as existing within the child, which has been the traditional way of looking at children's problems, but, rather, as aspects of the child's environment, ranging from the family and the school systems to the community and even the larger society. Deficits are evaluated for their potential impact on the child. Many families of color, particularly those that live in poverty, experience a number of ecological stressors that have a negative impact on their children's lives. "The ecological perspective is especially relevant in analyzing the impacts of poverty, discrimination, immigration, and social isolation on the psychosocial development and adjustment of minority children and youth" (Gibbs & Huang, 1998, pp. 6–7).

The Ethnic Validity Model

While suggested guidelines are helpful for cross-cultural practice, methods for systematically considering ethnicity and culture with assessment and intervention are needed (Barnett et al., 1995). A model developed by Barnett et al. (1995) shows promise as a framework for assisting school psychologists in conducting culturally relevant practice. The Ethnic Validity Model uses a problem-solving orientation that systematically considers cultural differences. The problem-solving model will not be detailed here (please refer to Tilly, this volume).

There are three key elements to the Ethnic Validity Model. The first key element is a *problem-solving orientation* that looks at problems holistically. In addition, the foundation of the model includes (a) establishing an advocacy role for the population being served and (b) accepting, respecting, and understanding the cultural values, perspectives, and behaviors of the population being served (Barnett et al.,1995). Throughout the problem-solving model professionals are always considering the cultural context as well as potential influences of culture on the problems situation.

The second key element is *acceptability*. This involves the participant's acceptability of the interventions being considered. There is a commitment to developing interventions that are compatible with the needs, values, and customs of the participant. Thus a participant's culture could be considered a factor in determining intervention acceptability.

The third key element is *teaming*. As teams use the Ethnic Validity Model, there are core features that support it. The core features of teaming are interaction and collaboration, ethnic group representation and participation, and distributed decision-making power. The ethnic group representation is seen as important in that it provides some measure of expertise with respect to culture. However, it should be noted that while this is an important feature, in reality it might be difficult to carry out, particularly in districts that are predominately white and where there are few staff members of color. In addition, some those staff members may choose not to serve in the role of being an expert on their culture. A solution may be the use of the community as an active participant of the teaming process. However, logistically this may be difficult. Another solution may be to hire a consultant whose expertise is cultural diversity. While this consultant may not be "present" at the teaming process, the consultant can help the team to evaluate its decisions within a cultural context.

Consideration of cultural variables should occur throughout all stages of the problem-solving model. Not considering cultural variables in the problem-identification stage could potentially result in the inaccurate identification of a problem, which could lead to an ineffective intervention.

The consideration of culture is not new. Individuals with Disabilities Education Act legislation has required teams to consider culture when working with children from diverse backgrounds.

Because culture, race, and ethnicity are considered sensitive topics by many, practitioners are often afraid to bring them up for fear they may be considered racist, because they feel uncomfortable discussing them, or because they lack the knowledge base to address or explore the issues in any depth. Culture should be considered as a factor in the same way gender, age, sex, single parent home, chronic illness, attention deficit disorder, etc., are considered in the assessment and development of interventions with children. If it does not contribute to the hypothesis of the child's problem, then it is discounted, but first it has to be considered.

SUMMARY

The population of the United States continues to be increasingly diverse. The challenge of school psychology is to prepare future school psychologists to practice in a culturally competent manner. This is particularly important given that only 5.5% of school psychologists in the field are people of color. It is essential that school psychologists learn to view each child in a cultural context with the goal of providing optimal services. In order to do this, school psychologists will need to become culturally competent. This involves developing a personal awareness, acquiring knowledge of other cultures, and applying the knowledge in skill-based practice. Being able to understand culture, as a continuum as well as understanding influences on culture, will, it is hoped, avoid stereotyping of groups. Effective cross-cultural practice relies on the practitioner's being able to both accept and respect human differences as well as the similarities. Little has been written in the literature to describe a systematic process or model for considering ethnicity and culture in the practice of school psychology. But, one model, the Ethnic Validity Model, shows promise as a framework for assisting school psychologists in conducting culturally relevant practice. An ecological perspective is also beneficial because it encourages the practitioner to view the child as an active participant in a system that is connected at all levels.

Becoming culturally competent is a process that will present some challenges but many more rewards. It is essential, however, if our goal is to provide effective services to an increasingly diverse student population.

This article reviews models of ethnic validity and how it can be used as a framework in the practice of school psychology. It also provides suggestions for incorporating ethnic validity in practice, training, and research.

Gibbs, J. T., & Huang, L. H. (Eds.). (1998). *Children of color: Psychological interventions with culturally diverse youth.* San Francisco: Jossey-Bass.
A must read for practitioners working with a group of children that is culturally diverse. This book provides an up-to-date analysis and guide to the unique problems and special needs of minority youth experiencing psychological and behavioral problems. An ecological perspective is the common thread through all the chapters and in the case studies.

Gopaul-McNicol, S., & Thomas-Presswood, T. (1998). *Working with linguistically and culturally different children: Innovative clinical and educational approaches.* Boston: Allyn & Bacon.
This book provides several models to help mental health professionals more accurately assess, treat, and consult when working with children from diverse backgrounds. Intervention strategies that are culturally sensitive are presented.

McIntosh, P. (1988). *White privilege and male privilege: A personal account of coming to see correspondences through work in women's studies.* Wellesley, MA: Center for Research on Women, Wellesley College.
The author looks at the privilege of "whiteness" and how it has advantaged some and disadvantaged others. Presents a frank discussion of race and racism in American society and how we can attempt to even the playing field.

Tatum, B. D. (1997). "*Why are all the black kids sitting together in the cafeteria?*" New York: Basic Books.
A practical and enlightening book that answers some of the commonly asked questions about race and racism. It will help the reader move to a new understanding of what racism is, how it affects us, and provides suggestions for what can be done about it.

26 Best Practices in Collaborating With Parents of Children With Disabilities

Marian C. Fish
Queens College of the City University of New York

OVERVIEW

Over the last 30 years there has been a steady shift toward greater collaboration between school professionals and parents of children with disabilities. As a result of deinstitutionalization, legislative, advocacy, and political efforts, parent participation in the education of their children with disabilities has increased substantially (Fine & Nissenbaum, 2000; Simpson & Zurkowski, 2000). This change in parent-professional relationships has influenced how school psychologists work with parents of children with disabilities, necessitating increased knowledge and skills in developing collaborative relationships.

Prior to the 1970s, parent-professional relationships were frequently characterized by parent submission to professional judgment, and the professional was expected to determine what was best for the parents (Seligman & Darling, 1997). Parents were expected to follow the recommendations of professionals rather than to participate in decision making (Turnbull & Turnbull, 1997). Fine and Gardner (1994) remind us that parents were often blamed for their children's problems and were treated poorly. This phase of involvement may be described as one of "passivity on the part of the parent" (p.284) and dominance by professionals.

During the second phase of parent-professional relationships many advances were achieved through court rulings and legislation. As a result of political advocacy and greater interest by professionals in the rights of families, there was a shift in policy toward mandated parent participation in educational planning for children with disabilities in the legislation of the 1970s. Rights given to parents in P.L. 94-142, the Education for all Handicapped Children Act of 1975, for example, included required notice and consent for evaluation, participation in decisions regarding evaluation results and at Individualized Education Plans (IEP) conferences. While parent participation increased, and many professionals recognized the importance of family involvement, parents were not always prepared for active participation, and school policies often did not truly encourage parent involvement. While improved, the model of help giving still fostered dependency of parents on professionals and was child centered.

The ideological shift that has brought us to the current phase of parent-professional relationships results from the acknowledgement that parents are usually the most consistent and caring people in the lives of their children (Roberts, Wasik, Casto, & Ramey, 1991), that parents have the right to participate in the development of programs for children, and that parents and families have strengths, resources, and expertise that can and should be used to meet the needs of their children (Fine & Gardner, 1994). This perspective was first seen in the Part H requirements of P.L. 99-457 (l986). This extended P.L. 94-142 to children below age five and required services to be directed at *families* through the Individualized Family Service Plan (IFSP), which includes a statement of family strengths as well as needs. This has been incorporated and extended in the latest reauthorization of the Individuals with Disabilities Education Act (IDEA).

The primary systems in the life of a child are the home and school, and the message of this legislation is that participation by each system and collaboration between these systems is necessary for the healthy development of the child.

School psychologists have always worked extensively with children with disabilities in special education and to varying degrees with their parents. Despite the clear benefits of cooperative involvement and collaboration, the active participation of parents of children with disabilities in the education process has not yet been fully realized (Fine & Nissenbaum, 2000). The "inclusion" movement, which supports placement of children with disabilities into the mainstream whenever possible, will likely further expand the need for the school psychologist to work with parents of children with disabilities in developing viable educational programs.

This chapter describes how school psychologists can effectively apply the philosophy of parent-professional collaboration in their work with children with disabilities. It recognizes that there is not one type of relationship between parents of children with disabilities and school psychologists. Clearly, the ultimate goal is to promote healthy family functioning and parent decision making and to empower parents through a collaborative relationship.

BASIC CONSIDERATIONS

The presence of a child with a disability in a family is a contributor to family stress and chronic in nature (Seligman & Darling, 1997). As many have noted (e.g., Fine & Nissenbaum, 2000), however, stress does not necessarily lead to dysfunction, but rather "a family is dysfunctional if it is unable to organize itself over time to cope with stressful events (p.4)."

When there is a child with a disability in the family, there is an impact on family functioning (Turnbull & Turnbull, 1997). "...children with disabilities inevitably challenge families by making inordinate demands on their time, psychological well-being, relationships, economic resources and freedom of movement (Brantlinger, 1991, p.250)." Until recently, much of the discussion on parents of children with disabilities has assumed homogeneity of family response, suggesting that all families respond in the same way (Seligman & Darling, 1997). While there are many similarities in functioning in families with a child with a disability, adaptation of these families can vary greatly and is influenced by a number of factors including ethnic and cultural background, nature of the disability, family position in the life cycle, and family structure.

To collaborate successfully with parents of children with disabilities, it is important for school psychologists to be aware of both commonalities and differences in functioning of families with children with disabilities. It is not only necessary to consider how these families are alike, but also to consider variables that contribute to the uniqueness of each family. Also, school psychologists should be able to recognize adaptive coping responses: What does healthy adjustment look like in families with children with disabilities?

COMMON FAMILY EXPERIENCES

Childhood disabilities have economic and psychosocial consequences for most families.

Economic Realities

Expenses related to a child with a disability often result in financial hardship for families (Turnbull & Turnbull, 1997). Although medical insurance may reduce some of the expenses for medical care, therapy, child care, and special equipment, it rarely provides for all needs (Seligman & Darling, 1997). Transportation, laundry, or structural modifications for the home to accommodate a child (e.g., ramps) or to repair damage are often costly (Fish, 2000). There are also indirect costs for these families such as lost work time and interference with career advancement. A chance to relocate to another city might have to be rejected because needed child services are not available, and this may prevent a parent from moving upward in his or her employment. Funds may not be available to provide for higher education and/or other needs of siblings.

Costs may be high not only for children with severe disabilities, but also for those with mild and moderate disabilities. For example, a child with a learning disability might need tutoring, summer programs, or a special computer (Turnbull & Turnbull, 1997). The economic impact on families with disabled children can be quite significant.

Daily Care Needs

The physical and health needs of children with disabilities often require great effort, particularly when the disabilities are severe or the illnesses are chronic. Daily care includes bathing, dressing, toileting, and feeding the youngster as well as cooking, cleaning, washing, and taking care of the household. Going to the doctor, to the supermarket, or to a fast food outlet can be a major undertaking. Once the child is dressed, the child must be taken in and out of transportation (e.g., car, bus) and moved from place to place. As children get older, it becomes more difficult for parents to accomplish these tasks. The responsibility of daily care over many years is associated with increased parental stress (Turnbull & Turnbull, 1997). One parent describes a shopping trip with her daughter who is retarded:

> When Beckie was little, such an excursion required only the extra energy needed to carry her on my hip and choose groceries one handed.... But, when she hit her teens a completely new ingredient was added to the challenge. I took her shopping with me only if I felt up to looking groomed, cheerful, competent, and in command of any situation, so that when she bellowed and stamped as she did when we walked through the supermarket door, people who stared could quickly surmise that I would handle the situation, quiet my strange child, and get on with my shopping (Turnbull & Turnbull, 1985, p.144).

Socialization Needs and Recreational Opportunities

It has been well documented that parents who have a child with a disability are less frequently engaged in leisure time activities and interact socially less with friends (Fish, 2000). Parents express feelings of isolation and find it more difficult to go on family trips, out to dinner, or to the movies. The mother of a child with mental retardation and cerebral palsy said "...it's really like having a little baby only he doesn't outgrow it. And we don't as a rule have people over because he doesn't go to sleep." (Seligman & Darling, 1997, p.65). Frequently, social life is limited because of the difficulties in finding a babysitter or care-giver who often must be specially trained.

Negative attitudes of community members are often cited as a major barrier to socialization for the whole family (Turnbull & Turnbull, 1997). For example, when disabilities are very stigmatizing (e.g., severely impaired speech) parents often structure their lives to avoid social situations where the child would have to speak, limiting their social interaction as well (Darling, 1991).

Future Planning Considerations

A major issue that must be faced is planning for the child when the child is no longer eligible for mandated services (Seligman & Darling, 1997). "Most parents of disabled children have concerns about the future from the day they suspect that something is wrong with the child" (Darling, 1991, p.81). They often ask, what if something happens to us? Uncertainty about the future with regard to employment, social opportunities, and legal/financial needs is a common worry that affects how a family plans events.

Parent response

Several theories have been proposed to explain the response of parents when learning that their child has a disability: stage theory and nonsequential stage theory (Brantlinger, 1991: Seligman & Darling, 1997). Stage theory suggests that all families go through a sequential series of stages such as shock, denial, sadness, anger or anxiety, adaptation, and reorganization before generally reaching a final acceptance stage. Nonsequential stage theorists agree that these reactions may be present, but they do not necessarily occur in a set order, and they may recur at different points in the life cycle. More recent opinions suggest that families may have similar responses, but if and when families pass through stages is dependent on a number of factors including both status (e.g., family size) and interactional variables (e.g., situational contingencies) (Seligman & Darling, 1997). It is probably useful to anticipate that family members will go through some process, but that it will vary depending on the individual family (Fine & Nissenbaum, 2000).

VARIABLES AFFECTING FAMILY RESPONSE

All families share many characteristics, and all children present a host of challenges and responsibilities to their parents, yet there is great diversity in family response (Hanson & Hanline, 1990; Powers, 1991). Many variables impact on the adjustment of a family to a child with a disability including child characteristics, parent ability to cope with stressors in general, parental beliefs about the cause of the disability, types and availability of both formal and informal systems and networks of support (e.g., family, friends, professionals), physician attitude, and prognosis (Hanson & Hanline, 1990; Seligman & Darling, 1997). Also, family background including socioeconomic status, ethnicity, and religion help determine a family's perception of its situation, the roles family members will play, and the family response (Seligman & Darling, 1997). For the purposes of this chapter, these variables affecting family response have been combined and organized as follows: nature of disability, cultural background, the family system, and the family's position in the life cycle.

Nature of the Disability

The nature, severity, and demands of the disability play a critical role in family response (Turnbull & Turnbull, 1997). Each type of disability has distinctive characteristics and functional behaviors that impact on the family. For example, when a child has a language or speech disorder, everyday communication may be affected (Turnbull & Turnbull, 1997). In one study, 28% of parents of children with a wide variety of disabling conditions indicated that the disability impacted on the daily lives of the family. The effect was "clearly more pronounced among the families of children with more substantial handicaps and rises to 60% for families of children with physical/multiple impairment" (Palfrey, Walker, Butler, & Singer, 1989, p.102).

The physical appearance of the child with a disability can influence family reaction. A very visible handicap may affect not only the child's self-concept, but also the attitudes of parents, siblings, and others in the community. Severe disabilities that are more visible may excuse inappropriate behavior or may cause social stigma (Turnbull & Turnbull, 1997). It is not clear, however, that parents always share a common view of severity of handicap (Blacher, 1984). Ambiguous conditions such as autism or those with uncertain prognoses are hypothesized to be the most emotionally stressful for families as parents often keep searching for plausible diagnoses or appropriate treatment (Brantlinger, 1991). Genetic disorders have broad implications because parents may be carriers of the trait (Brantlinger, 1991). A thorough understanding of parental feelings about the handicap and of family expectations for the child is essential.

Of course, a most critical aspect of the disability is the functional behavior of the child. It is not the disability itself that is the key, but the resulting behavioral characteristics that affect the family.

Cultural Background

Culture permeates all aspects of family life including childrearing practices, beliefs about education and disability, and even how the family accesses health care (Correa & Jones, 2000). There is great diversity of reaction to childhood disability dependent on cultural groups such as social class, ethnicity, and religion. There is, however, considerable confounding in studies of ethnic groups, religious groups, and social class.

SOCIAL CLASS

The clearest examples of social class differences have occurred in studies with children within the mild ranges of retardation. Parents and professionals from middle- and upper-class families regarded even mild retardation as devastating, "while lower-class parents may not even define it as a disability (Seligman & Darling, 1997, p.174)." Possible explanations suggest that lower-class families are not as achievement oriented and are able to envision their child in normal adult roles, or that they have a higher tolerance for deviance. In the case of a physical disability, however, there appeared to be no differences by social class. A recent study reported that lower-class families had less family support and more physical, emotional, and financial problems than higher class families (Seligman & Darling, 1997). It is hypothesized that when necessities are scarce, the child's disability is only one of a myriad of problems and may not get the same attention as in more affluent families. Parents from different socioeconomic groups report stress differently and behave differently with regard to participating in program planning (Palfrey et al., 1989).

ETHNICITY AND RELIGION

Attitudes toward disability in our society vary by ethnicity and religion, yet we must be careful not to stereotype any group because there is much intragroup variability. Research on African-Americans, for example, indicates that they place great importance on the extended family and the church as social supports, and that they report a greater number of significant others who assist families with a disabled child (Seligman & Darling, 1997). Hispanic subcultures include Mexicans, Puerto Ricans, and subgroups from many Latin American countries. Traditional Mexican culture values of familism, male dominance, subordination of young to old, and person orientation rather than goal-orientation may result in Mexican-American parents being more accepting of disability than Anglo parents. Similarly, family strength and support is very important in the Puerto Rican community along with submissiveness and acceptance of fate; that is, such "fatalism may help parents cope with a child's disabilities" (Seligman & Darling, 1997, p.186). Another example where culture may play a role is among Asian-Americans. In Chinese culture, for example, family problems may be viewed as private, and sharing them with outsiders may be considered shameful (Seligman & Darling, 1997).

There is little evidence for a relationship between any religious group and acceptance of disability. It is suggested, however, that more religious families may have support networks through their place of worship (e.g., church, synagogue, mosque) that may facilitate acceptance and coping (Seligman & Darling, 1997).

It is clear that cultural background is a significant factor in family adjustment to a child with a disability and that it also affects family responsiveness and receptivity to sources of help (Fine & Gardner, 1994).

The Family System

Families are interdependent systems where change in any member affects all other members. Family structure refers to the characteristics of the family, its members, and its organization. Persons in the family (mother, father, siblings, grandparents) join in subsystems to perform various tasks or functions, and all members of the family have different roles and responsibilities (Fish & Jain, 1988; Powers, 1991). Family structure should be taken into account when considering family response to a child with a disability.

NONTRADITIONAL FAMILIES

An increasing number of children with disabilities are being raised in nontraditional households, such as single-parent, blended, or gay and lesbian parent homes (Fish, 2000). An overwhelming majority of single parents, 90%, are mothers who work outside the home (Carlson, 1995). While the functions of the single-parent family are the same as the two-parent family, when the custodial parent tries to carry out both functions, role strain may result and affect the system (Fish, 2000). On the other hand, in blended families where one or both partners have been previously married, a major structural issue is the lack of clear role definition and clear boundaries. There are now more than two parents with potential conflict in such areas as visitation, life-style, and/or discipline (Fish, 2000).

Recently, there has been interest in gay and lesbian households. Because adoption is often difficult for same-sex couples, they are frequently willing to adopt children who are hard to place such as children with disabilities. Fear of social discrimination and less external support often isolates them to an even greater extent than heterosexual families with a child with a disability (Fish, 2000). These examples illustrate that alternative family structures must be carefully considered and play a critical role in adaptation when there is a child with a disability.

SIBLINGS

Some research suggests that siblings of children with disabilities may be prone to adjustment problems, while other literature indicates that nondisabled siblings may benefit by developing responsibility, competence, and independence (Mason, Kruse, Farabaugh, Gershberg, & Kohler, 2000). These inconsistent findings may be the result of differences in extent of care taking by sibling, restriction of sibling's social life, excessive time and attention paid to the child with the disability by parents, and the number and gender of children in the family (Seligman & Darling, 1997). Several studies suggest, for example, that older female siblings in small families may have more extensive care-taking responsibilities than other siblings. Generally, it is reasonable to say that siblings of children with disabilities may be considered at risk.

It is apparent that family subsystems (mother, father, parents, siblings), all affect and are affected by the child with a disability in the family and contribute to the uniqueness of each family's adjustment.

Life Cycle Position

Families progress through identifiable stages in their development (Carter & McGoldrick, 1989). Whether these are crises or transitions depend on the ability of a family to modify its structures to accommodate changing needs. There are educational and developmental milestones where parents must confront limitations and strengths of their child (Fine & Nissenbaum, 2000). A survey of the literature suggests that major stages for families with a child with a disability are at preschool age (3–5 years), school age (6–8 years), adolescence (12–14 years), and chronological adulthood (19–21 years) (Beavers, Hampson, Hulgus, & Beavers, 1986; Powers, 1991). For example, with a child with retarded development during the early years, there are issues concerning the child's physical health and safety, parent adjustment to a diagnosis, and readjustment of expectations (Powers, 1991). When the child with a disability reaches school age, parents may be forced to acknowledge their child's widening differences from other youngsters. For parents of children with retarded development the onset of puberty increases their awareness of differences between their child's physical appearance and the child's mental and social abilities (Wikler, 1981). The adolescent may have increased wishes for independence, and the child's emerging sexuality is evident. At a time when the nondisabled adolescent is entering independent adulthood, the adolescent with a disability is often still dependent on his or her family. Parents who anticipated increased freedom and independence in personal, professional, and family areas must readjust their expectations (Dane, 1993). In one study of development and transition, 30 parents of mentally retarded persons characterized their child's twenty-first birthday as the second most stressful of 10 predictable crises (Wikler, 1981).

ADAPTIVE COPING

Despite oft-repeated statements of greater chronic dysfunction in families of children with disabilities, there is little evidence that supports the presence of greater psychopathology among these families (Hampson, Hulgus, Beavers, & Beavers, 1988). Although some families adapt to the stress of a child with a disability better than others, most families manage to adapt quite well to the needs of a child with a disability.

In a study of families with a retarded child, for example, observed family competence was within the adequate range and compared favorably to the nonclinical group of families (Hampson et al., 1988). Characteristics that were associated with healthy adaptation included: openness and directness of communication, strong internal support systems, a noticeable degree of autonomy and responsibility in all members, and few signs of unresolved conflict. Expression of feelings did not necessarily have to be positive, but could be negative or ambivalent and still indicate good coping.

In another study, family adaptation was promoted by clear diagnosis and information about the disability and the capability for positive contact with and response to other family members (Beavers et al., 1986). Families that acknowledged the extra needs and the "differentness" of the disabled member, while giving other family members' needs and views equal weight, were most competent. In these families there was an effort made to balance the special needs of the child with the disability with other family concerns (Beavers et al., 1986). Still other studies have reported that adequate social supports, and financial and personal resources such as family integration, parental self-esteem, and physical and emotional health, were associated with fewer negative consequences (Todis & Singer, 1991). Morgan (1988) reports that family cohesion, expression, and recreational orientation, as well as the mother's perception of adequacy of support from the husband and other relatives, were associated with better adaptation to an autistic child.

In general, certain family characteristics appear to be associated with healthy adjustment. These include good communication among the family members, supportiveness of family members toward each other, problem-solving skills, and the ability to assume appropriate parent and child roles (Fine & Gardner, 1994).

BACKGROUND AND TRAINING

Collaborating successfully with parents of children with disabilities requires that school psychologists move from a child-centered model to a family-centered model. A family orientation in school psychology is not synonymous with family therapy, but rather refers to consideration of the child within the family context and views the family as a system of interacting members.

A family-centered model recognizes that families have strengths and supports, and it appreciates their diversity and uniqueness. An understanding of similarities and differences among families and recognition of adaptive functioning as discussed above is essential. A knowledge base in family systems is required as all members of a family influence and are influenced by other members. Any change or stress in the family, such as the presence of a child with a disability, has an impact on the family system. The family is a dynamic entity and should be approached in a manner that recognizes the developmental and cyclical nature of adaptation (Bailey & Simeonsson, 1988).

A family orientation does not subscribe to a deficit model, but rather it builds on existing family competencies and helps develop new competencies so that a family can actively advocate for itself.

In addition to a family-centered systemic perspective, knowledge on the part of the school psychologist about the contemporary family; the cultural/ethnic background of families within their school district including their values, traditions, beliefs, and view of health care; relevant community resources; and the specific disability and the behavioral aspects of the disability is helpful when working with families with a child with a disability.

Without question, the school psychologist must also be very much aware of one's own attitudes and beliefs. Insight into one's own cultural values and preconceptions and assumptions about the family are prerequisite to understanding and respecting others' values.

Training in consultation skills will facilitate interactions with parents and the development of a collaborative relationship. Fine and Gardner (1994) note five "process skills" that support the enactment of collaboration: (a) interpersonal skills (e.g., accurate listening and communicating, (b) language considerations (e.g., "we" rather than "I" statements, respect for others views), (c) problem-solving skills, (d) recognition of family prerogatives, and (e) ability to personalize assessment (e.g., assess families with regard to structure, function, strengths, and resources) (p.299).

Table 1 illustrates the types of helping behaviors likely to be enabling and have positive consequences (Dunst & Paget, 1991, p.36).

It is also important for the school psychologist to be able to identify potential obstacles to a parent-professional relationship and have the skills to overcome them. Fish (1990) describes barriers to family-school relationships that may stem from philosophical, attitudinal, or logistical factors and/or skill deficits on the part of those involved. Similarly, Christenson and Hirsch (1998) identify conditions that may create conflict between the home and school. Sometimes the obstacles are bureaucratic and require organizational change, yet often the interference stems from lack of trust or poor communication. Weiss and Edwards (1992) have developed a series of exercises that help the professional learn how to take typical blaming statements, block the blame, and refocus a situation onto problem solving.

BEST PRACTICES

Traditional means of working with parents of children with disabilities have often been paternalistic and have led to dependency on the professionals. Despite pleas for family involvement, there has often been a disparity between the approach to helping, which views the school psychologist as being the authority with all the answers and the behaviors necessary to promote greater participation on the part of the family (Dunst & Paget, 1991).

A number of models have been proposed for working with parents of children with disabilities that have attempted to address this conflict. The model developed by Dunst et al. (1992), for example, sees parent-professional partnerships as a function of interactive time between parents and professionals and the display of different behavioral states and traits such as trust, honesty, and shared responsibility (p.170). This model shows how relationships evolve from coordination to cooperation to collaboration and finally to

Table 1. Help giver attitudes, beliefs, and behaviors associated with empowering and competency-producing influences

Prehelping attitudes and beliefs	*Helping behaviors*	*Posthelping responses and consequences*
1. Positive attributions toward help seekers and helping relationships.	1. Employs active and reflective listening skills.	1. Accepts and supports help seeker decisions.
2. Emphasis on help seeker responsibility for meeting needs and solving problems.	2. Helps client clarify concerns and needs.	2. Minimizes the help seeker's sense of indebtedness.
3. High expectations regarding the capacity of help seekers to become competent.	3. Pro-offers help in response to help seeker needs.	3. Permits reciprocity as part of help giver–help seeker exchanges.
4. Emphasis upon building on help seeker strengths.	4. Offers help that is normative	4. Minimizes the psychological response costs of accepting help.
5. Proactive stance toward helping relationships.	5. Offers help that is congruent and matches the help seeker's appraisal of needs.	5. Enhances a sense of self-efficacy regarding active involvement in meeting needs.
6. Promotion emphasis as the focus of giving help.	6. Promotes acquisition of competencies to meet needs, solve problems, and achieve aspirations.	6. Maintains confidentiality at all times; shares information only with help seeker's permission.
	7. Employs partnerships and parent-professional collaboration as the mechanisms for meeting needs.	
	8. Allows locus of decision making to rest with the help seeker.

a partnership "as parents and professionals work toward agreed upon goals" (p.169). Reaching a true partnership relationship is a process that takes time. Table 2 (Dunst et al., 1992, p.163) presents a categorization scheme for organizing the major characteristics of parent-professional partnerships as identified by *both* parents and professionals. These characteristics can be used by professionals as guidelines to evaluate their own performance with regard to attitudes, beliefs, and behaviors.

A collaborative model of parent involvement is presented by Fine and Nissenbaum (2000). Its objectives are (a) to include parents in decision making; (b) to educate parents for participation in decision making; (c) to assist parents therapeutically, as needed, so they can cope with specific impediments to their participation; and (d) to enable and empower parents to work actively on behalf of their child. As with the parent-professional partnership model of Dunst et al. (1992), collaboration is a desirable goal that takes time to achieve. Laborde and Seligman (1991) propose a model of intervention for working with families of children with disabilities that has three counseling interventions: educative, personal advocacy, and facilitative counseling (p.161). The educative role is one of providing information to parents, and personal advocacy refers to assisting parents in finding relevant information and locating appropriate services but being careful to help parents assume this role themselves. Facilitative counseling is similar to supportive counseling or psychotherapy to help parents deal with feelings or behaviors of concern and to build coping behaviors.

A review of these and other models suggests that there is considerable agreement as to what effective relationships between school psychologists and parents look like and much consensus on the means to achieve these goals. Best practice in working with parents of children with disabilities has as its goal collaboration and/or partnership with parents using approaches that empower, encourage participatory involvement, and enhance competency (Dunst et al.,

Table 2. A categorization scheme for organizing the major characteristics of parent–professional partnerships

Category	*Definition*	*Characteristics*
Beliefs	Cognitive attributions about how one should act or ought to behave toward other people	Trust, mutual respect, honesty, acceptance mutually supportive, nonjudgmental, presumed capabilities
Attitudes	Particular (emotional) feelings about a person, situation, or relationship	Caring, understanding, commitment, empathy, positive stance, humor, confidence
Communicative style	Methods and approaches for information sharing between partners	Open communication, active listening, openness, understanding, full disclosure of information, information sharing
Behavioral actions	Behaviors that reflect translation of attitudes and beliefs into actions	Mutual respect, openness, flexibility, understanding, shared responsibility, mutual support, reciprocity, mutual agreement about goals, dependability, equality, humor, problem solving

1992). One family describes a successful collaboration with a professional:

> The most important aspect ... was that he involved us as equals in the decision-making process.... By involving us in the process and by giving us his professional opinion as an opinion, he returned to us our parental rights of making the important decision that would affect our child's life. We were in control, but were no longer alone (Seligman & Darling,1997, p. 217).

Professionals move in and out of the life of the child, but parents provide constant support for their children and hold ultimate responsibility for their well being.

Best practice in working with parents of children with disabilities include the following services:

Education/Information Sharing

The role of providing information means that school psychologists help parents obtain information, understand and interpret information, or use information to help make decisions. The types of information can include behaviors associated with the disability, characteristic patterns of development, health or related services, and community resources. Care must be taken to assure that siblings and/or other family members are informed during this process as well.

Information needs will vary at different age periods. For example, diagnostic and prognostic information is generally conveyed at earlier ages (Seligman & Darling, 1997). On the other hand, information on sex management and sources of vocational training is more likely to be requested during adolescence. Other information needs are quite consistent across ages and include inquiries about respite services, financial assistance, support groups, and appropriate child care providers. At all ages parents may want practical information regarding management, specialized equipment, or legal rights that may be provided through books and other reading materials, referrals to community organizations, as well as direction to online resources. A list of 60 books written by parents of children with many different disabilities has been prepared by Mullins (1987) and is a useful resource. *The National Information Center for Children and Youth with Disabilities* (NICHCY, P.O. Box 1492, Washington, DC 20013-1492; www.kidsource.com/NICHCY) is a national information and referral clearinghouse and provides material for parents and professionals. Also, the *Federation for Children with Special Needs* (FCSN, 1135 Tremont St. Boston, MA 02120; www.fcsn.org) is a coalition of parent groups representing children with a variety of disabilities and working on behalf of their families. Other online resources are available as well.

Because information may come from many sources, Powers (1991) sees one role of the school psychologist as facilitating and coordinating service access. As a liaison to medical, educational, social, and financial services, the school psychologist can slowly transfer this knowledge of services to the family. One father's plea for such a coordinator is seen here:

> ... it seems that ever since Joan was born, everything has changed ... there always seem to be at least three experts around giving Judy advice on how to handle Joan.... I know that my son Jimmy has been having some problems, but the thought of another expert ... is more than I can take. I wish we could find one person who could pull all the information together (Family Life, 1985, p.50).

Once all the information is gathered, parents may choose to collaborate with the school psychologist in decision making. An essential aspect of this collaboration is that parents be given options whenever they exist so that they can make educated decisions on behalf of their child.

A problem-solving approach involving problem identification and analysis, brainstorming alternatives, and choosing a plan of action not only is a collaborative process but also models the problem-solving procedure for families. One family member pleased by a collaboration said of the professionals:

> ... They gave us ideas to get him into the setting. They never took control out of our hands, and we always did the steps ourselves. They were there as a resource and support. The staff helped me to gel the vision (Seligman & Darling, 1997, p. 218).

Helping to assure an appropriate match between family needs and service opportunities is a critical responsibility of the school psychologist. Providing services that are congruent with the needs of family may mean problem-solving with parents on the phone rather than in person so they don't miss work. Care must be taken not to overburden families, but rather to reinforce their decision-making abilities.

Advocacy

Advocacy "refers to the process of aiding parents to actively and purposively work for their own and their child's welfare by obtaining the support and services they need" (Laborde & Seligman, 1991, p.361). This may involve overcoming physical barriers (e.g., stairs), cultural barriers (e.g., prejudice), or social barriers (e.g., needed services) (Seligman & Darling, 1997). The school psychologist has the requisite knowledge about how agencies operate and how referral services work as was seen in the education role described above. Powers (1991) suggests that the school psychologist move from being a direct advocate for the child and family to being a consultant to parents in the advocacy process. Once again this means a relinquishing of authority on the part of the school psychologist and supporting the family as it asserts itself.

Support

Social support has been identified repeatedly as a key component in healthy family adaptation and coping. Support networks can be formal, such as organized groups run by the Arc (organization on mental retardation) or the local school, or informal such as family, extended family, and friends. Often families have resources other than the schools and its activities available to them. For example, the place of worship may be a nurturing environment for its members. Maintaining existing social networks and developing new social networks help reduce the social isolation and stresses of the family with a child with a disability. Turnbull and Turnbull (1997) provide a list of statewide parent-to-parent programs, parent training and information centers, and grassroots organizations. Of particular importance in all cases is to consider not only support for mothers but also support for fathers and siblings.

Facilitation of Healthy Family Functioning

Promoting healthy family functioning requires school psychologists to support the structural balance within the family including clear boundaries between parental and child subsystems, the executive function of the parental subsystem, and a healthy relationship between the parents (Powers, 1991). It is important to acknowledge the extra needs and differences of the child with the disability but without neglecting other family members. Remember, parents have needs beyond those of educating their children. Family competencies and resources can be assessed informally or through the use of specific assessment measures such as those described by Bailey and Simeonsson (1988). Noncustodial parents should be included in decision making when appropriate, and information should be sent to all involved adults.

Parents must determine if they want help and what kinds of help they need. Some ways to assist families might include helping them to minimize or better manage time demands and/or to encourage parents to maintain their own health through such means as exercise or vacations. Another suggestion is to hold informal family meetings weekly to review household responsibilities and to discuss concerns.

Individualization of Services

In all cases the relationship between the school psychologist and the parents is an individualized one taking into consideration racial, ethnic, cultural, and socioeconomic diversity as well as the nature of the disability, family structure, and life cycle position. For example, early childhood consultation regarding young children with disabilities is qualitatively different from consultation when children are in elementary and secondary school settings (Mowder, 1994). These younger children are developmentally more dependent on parents and families for their care and protection (Mowder, 1994). Parents should never be expected to function in only one way, and school psychologists must match services to need.

Group Approaches

There are a number of reasons why group approaches are well suited for parents of children with disabilities (Fish, 1998; Gettinger & Guetschow, 1998). Groups bring together parents with similar experiences and can be effective in meeting parental needs for information, social and emotional support, encouragement, and assistance in problem solving (Gettinger & Guetschow, 1998). By participating in a group parents may develop more realistic expectations about their child, may become more self-confident, and may be empowered to make more effective decisions. Parents offer a wide array of coping behaviors from which other members learn (Fish, 1998). Also, feelings of social isolation are minimized through group work.

Groups for parents with a child with a disability may serve educative/training and/or therapeutic functions (Fish, 1998). The common core elements of parent groups are peer support, vicarious learning, mutual helping, reality testing, and the fostering of friendships (Gettinger & Guetschow, 1998). There is growing recognition that support is needed not only by the mother of a child with a disability but also by other family members, especially fathers. Siblings and grandparents may be the focus of support groups as well (Fish, 1998).

Other Best Practices

Best practices in working with all parents should be applied to families with disabilities as well. Some examples include avoidance of jargon, flexible scheduling, addressing correspondence to both mother and father, considering siblings, and establishing a relationship before there is a crisis (e.g., Fish, 1990). Parent-teacher contacts will likely increase as a result of including more children with disabilities in mainstream classes. School psychologists can assist teachers and other school personnel in acquiring skills important for successful collaborative relationships with parents.

SUMMARY

This chapter has identified a number of common experiences among families with children with disabilities. These are economic constraints, daily care needs, socialization needs, and worries about the future. Though these families share many concerns, each family is unique, and a number of variables impact on their adjustment including the nature of the disability, the cultural background, the family structure, and the family's position in the life cycle. Adaptive functioning in families with children with disabilities is associated with good communication, strong support networks, and clear boundaries between subsystems.

Collaborating successfully with parents requires school psychologists to adopt a family-centered approach to services. This is reflected in a non-blaming perspective where family strengths and resources are recognized and supported and different methods of coping are respected. The goal is one of collaboration with parents to enable and empower them so that they may help themselves. This involves the development of trust, respect, mutual commitment, and sharing. Empowerment of parents is facilitated by the school psychologist through information sharing, advocacy, support, promoting healthy family functioning, and through individualization of service to each family. Collaboration can be through group work as well. In all of these roles the school psychologist aims to increase parental involvement so that the parents assume the role of decision makers for the family.

ANNOTATED BIBLIOGRAPHY

Fine, M. J., & Simpson, R. L. (Eds.). (2000). *Collaboration with parents and families of children and youth with exceptionalities* (2nd ed.). Austin, TX: PRO-ED.

This book views parents as partners with the professional community in the care, treatment, and education of their child with a disability. It has as its theme the empowerment of parents through a collaborative relationship with professionals. The book presents a collaborative-empowerment model, provides educational and intervention considerations, examines the impact of different exceptionalities on the family, and discusses issues including sexuality, transitions, and advocacy.

Seligman, M., & Darling, R. B. (1997). *Ordinary families, special children: A systems approach to childhood disability* (2nd ed.). New York: Guilford.

This book examines the child, family, ecological, and sociocultural variables that contribute to the response of families to childhood disability. Writing from a systems perspective, the authors discuss the impact of a child with a disability on the family from birth through adulthood. Information on intervention strategies and services for families is provided.

Turnbull, A. P., & Turnbull, H. R. (1997). *Families, professionals, and exceptionality: A special partnership* (3rd ed.). Columbus, OH: Merrill.

The theme of this book is empowerment of parents through collaboration. By using a family systems perspective, the authors provide both theoretical and practical information and infuse multicultural issues into the text. Parent perspectives are clearly provided.

27 Best Practices in Facilitating Meaningful Family Involvement in Educational Decision Making

Dawn D. Hubbard
Northeast Kansas Education Service Center, Lecompton, Kansas
Jane Adams
Keys for Networking, Topeka, Kansas

OVERVIEW

"The way schools care about children is reflected in the way schools care about the children's families" (Epstein, 1995, p. 701). Schools need families as much as families need schools. Schools especially need families when children are not adequately progressing in the general education curriculum. A problem-solving approach for how school-based teams respond to academic and behavior concerns can meaningfully involve families at every step of the process. With the problem-solving approach used across the continuum of difficulties and with continuity of team members across the decision-making process, families and teachers can stay focused on the child and the child's needs.

Historically, including parents in meaningful ways has been very difficult for both educators and parents, especially when it involved special education decision making (Adams et al., 1998). With the categorical medical models that evolved through the 1970s, outside experts drove the special education process for parents and for schools. Because experts determined the methods of assessment and the procedures to obtain educational supports for individual students or teachers, lay people (classroom teachers and parents) simply abdicated their responsibility. The 1990s brought new emphasis on comprehensive school reform and school-based decision-making, and parents, as well as teachers, now have new roles. Previously, family involvement consisted to a school expert explaining the eligibility process and criteria of the family. Now, best practices in family involvement utilize a school-based problem-solving team that includes parents to assess strengths and to formulate and evaluate interventions and to collectively make decisions (this is depicted in Table 1).

This chapter identifies new strategies for reconceptualizing family involvement based on a school-based team-centered planning model. Described are the essential elements including composing a school-based team, using strengths-based problem solving, using joining language, sharing decision making, and connecting families to individual teams, to other parents, and to the school. This chapter then concludes with best practice examples that demonstrate the efficacy of the model.

Changes in Evaluation and Service Delivery Models

The challenges faced by parents and educators in classrooms of the twenty-first century exceed in complexity what the traditional expert-driven assessment process offers. The prevailing model of the past century provided categorical assistance to children failing to make adequate academic or social progress. Figure 1 depicts a local education agency's categori-

Table 1. Family involvement continuum

Expert-driven	*Family-allied*	*Family-centered*	*Team-centered*
The traditional model of involvement considers the professional to be the expert and views family members as recipients of information. The professional-parent partnership is typically uncomfortable and business-like. Parents may be viewed as adversarial if they ask questions or have conflicting opinions. They are rarely asked for input.	This attitude views families as allies of services. The caregiver is seen as a more equal colleague, one who has expertise, knowledge, and choice. School professionals and family caregivers work together to address mutually agreed upon goals. The family depends on the advice of professional staff who directs the family's interactions with the child.	This philosophy puts school professionals "one down" to family caregivers in the child's team. School professionals believe family caregivers know what is best for their child. School professionals help the family achieve family goals for the child. School team members ask, "How can we help you? How can we be of service to you? What do you need from us?" Decisions and the responsibility rest with the family.	School-based practice centers decision making with the building team. Team strengths (which include the family and the child) are used to select interventions most likely to work. The team-centered problem-solving model depends on the combined skills and resources of the team. Responsibility for decisions rests with the collective power of the team's working together supporting each other as well as supporting the child and family.

cal compensatory, supplemental, and special education responsibilities, procedures, and outcomes. Local education agencies, through many state accreditation requirements, have the responsibility of ensuring that students demonstrate continuous academic and social improvement. Classroom teachers must design, implement, and monitor instructional strategies when students fail to demonstrate adequate progress according to performance on state or local assessments. When student problems are more severe than classroom teachers can resolve, districts offer program supplements to the general education curriculum. This array of programs may be federal or state funded, optional or mandatory, such as Title I, after school and Saturday tutoring activities, at-risk prevention programs, and the range of federally prescribed special education services.

Since the mid-1970s local education agencies have held the responsibility of locating and identifying students with disabilities. Both the Individuals with Disabilities Act (1997), and Section 504 of the Rehabilitation Act (1975) require school personnel to find children in need of services and supports and to include families in the decision-making process. With the 1970s reliance on outside experts to ensure that appropriate learning opportunities were provided, and the 1980s and 1990s caveats to decrease unnecessary referrals for special education, the outcome, though unintended, has been to remove ownership of the problem and its solutions from the school and, unfortunately, from parents.

Historically, when external experts have driven the process, classroom teachers and parents are omitted from finding solutions to problems. Both teachers and parents seem relegated to signing documents. When building staff waits for directions from external experts, fragmentation and inefficiency block the effective use of building resources and meaningful decision making by people who best know the student and each other. It delays meaningfully connecting the student to interventions and hinders teachers from connecting to parents and each other.

Figure 2 depicts how educational responsibilities can be addressed in a less fragmented manner with school-based problem-solving teams supporting access to individualized student interventions for any student (Kansas State Department of Education, 1999). The school-based team approach engages and empowers those who work with students daily and develops their capacity to deliver what students need. The focus becomes "what does it take to make this student and this teacher successful together." While helping individual students, this approach also builds the school's capacity to connect teachers, family, and community resources to each other. If the school team suspects the student is a student with a disability on

the basis of the child's response to the interventions, then the relevant team members and necessary experts join to form an eligibility team. The student performance data previously collected are shared so that further assessment is non-duplicative. The team focuses on functional and meaningful assessments to guide confident decision making.

Team-Centered Approach and a Problem-Solving Model

With systematic problem solving, the school teams, which include parents, collect and analyze data to develop, implement, and monitor interventions for their effectiveness (Tilly, this issue). The problem-solving approach is constant, whether used by a team, which is composed of the classroom teacher and parent, or an extended school-based problem-solving team of six to eight people. Keeping the problem-solving concept constant allows access to varying levels of resources, depending on the presenting concern as depicted in Figure 3 (Heartland Area Education Agency, 1994; Reschly & Ysseldyke, 1995). A small team often successfully carries out problem solving, as indicated by the size of the first circle. For example, the classroom teacher and the parent meet to discuss a concern the parent or the teacher has about a child's reading performance. Together they discuss

their observations, consider the teacher's classroom data, and propose an intervention. The intervention plan may be as simple as sending supplemental reading materials home for an adult to use with the child. It may have the child read with an older student at school. If the intervention works, then no further problem-solving efforts are needed. When the intensity of the concern exceeds classroom and home resources, or when the student, parent, or teacher asks for more extensive assistance, the parent-teacher team adds members who have varying levels of expertise and experience. If the school team suspects the student may be a student with a disability, then the team may invite necessary experts, such as the school psychologist or behavior specialist, to continue problem-solving efforts as part of the initial evaluation process. The continuity of team members is critical for teachers, and especially for families. For families, the more team members remain constant and represent the people who serve the children daily at the school, the more parents trust the process. The more trust they have in the process, the more parents will participate.

BASIC CONSIDERATIONS

School-based teaming invites and engages families as meaningful participants. By using lay language and enlisting the strengths of individual team members to propose interventions facilitates understanding and defines outcomes so that the success or failure of the interventions becomes clear.

Design and Explanation of Process

Each school-based team determines how the school will make the process fair and accessible to students, families, and the community. In this model, school psychologists use their expertise to connect and coordinate multiple service systems (e.g., mental health, education, social services), develop and nurture the partnerships between the school and community agencies, and train teachers to work alongside parents.

In this role, the school psychologist can also assist to set policies that invite families that are, or are likely to become, customers of extensive supports. Developing policies and procedures with the people most affected assures those policies and procedures will work for them. For example, asking family members to review letters and brochures that explain the process to other parents will result in clear, easy-to-read descriptive language, understandable to the families the information is designed to reach. Furthermore, the school psychologist may suggest strategies to let families know how to access help and how to design interventions for their own child. Awareness activities may include talking with the local PTA, writing an article in the local or school newsletter, making brochures available in the community, and/or asking family advocacy organizations to disseminate the process. The school psychologist may recommend to the school team families that have been through the process to explain it to other families. Parent liaisons can talk effectively with other parents about what the process will look like, the importance of the parent's role on the team, and the value of information they bring to the team. Peer-to-peer consulting (parent-to-parent, teacher-to-teacher) increases the acceptance and involvement of all members. For example, if a teacher seeks assistance from the school team, then the teacher is likely to respond more favorably when working with another teacher than when working with a principal. Parents are more likely (especially parents who may have had less than a positive experience with school meetings) to listen to other parents, and are more likely to ask questions. Peer-to-peer discussions allow and even establish open and honest exchanges regarding fears associated with having a child experiencing academic and/or social difficulties in school. The school psychologist can define and support this process of parent-to-parent, teacher-to-teacher mentoring.

Designing Interventions Based on Strengths

With the teacher and the parent as core team members, strengths assessments engage the teacher, the families, and the student. It also connects the school staff to each other in new and more positive ways. Assessing the environment and people for their strengths has been widely adopted as successful in mental health-driven wraparound planning (Goldman, 1998; VanDenBerg & Grealish, 1996). In the strengths assessment, team members define together the *functional* strengths of each team member. With the school psychologist facilitating this process, team members point out positive aspects of each team member, and they look for what works for the teacher, the student, and for the parents. When team members make their strengths explicit during intervention planning, the team members can draw upon their own strengths to design and evaluate the potential of each intervention prepared. When interventions utilize strengths, the likelihood is increased that (a) the interventions will be successful and (b) they will be implemented by the student, family, and classroom teacher.

For example, when a school-based team considered the problems of a 5-year old student experiencing difficulty getting along with peers in the lunchroom, the mother shared her observations that Joshua's lunchroom behavior depended on the lunchroom supervisor. This information offered a new insight to the team. As team members recognized this mother's ability to offer insights and report her observation, they identified one of the mother's strengths as listening to her child and knowing the school environment through her child's eyes. The team, which included Joshua's mother, designed an intervention plan and had the mother monitor and chart Joshua's behavior. The school psychologist assisted in setting up the chart while the teacher agreed to visit with the principal about training for the lunchroom supervisor.

Capitalizing on each member's strengths increases participation, builds ownership of the process, and creates bonds between school and home and among team members. The team becomes accountable to its members based on the resources they bring.

Joining Through a Common Language

Attending to strengths of individuals and the use of positive interactive communication keeps both parents and teachers engaged in the problem-solving model. The school psychologist may help parents and the child's teachers reframe what they know about the child so that a powerful strengths-based plan is developed and confident educational decisions are made. Keeping the meeting free from jargon and holding conversations to strengths assures that each team member is comfortable and confident to ask questions and offer resources during the meeting. Teams should assign a team member the task of ensuring the focus on strengths and clarifying possible "jargon." The person who assumes this role asks for examples and clarifies issues during the meeting and assures the focus on strengths. The team should consider asking the student to serve as the "jargon buster." In this role, the student can have a dignified opportunity to ask for clarity, have an chance to talk, and is provided a structure for participation.

Holding conversations to strengths often involves reframing the information that is brought to the table. The school psychologist can teach the team to reframe problems in terms that allow them to design more powerful intervention plans. Interventions based on strengths of the team have an increased probability of succeeding (VanDenBerg & Grealish, 1996). For example, discussing the student's ability to share the details of his school day with his mother and to examine the school environments where he has success removes the jargon of categorical labels, placement terms, and diagnoses and focuses the discussion on what works and what is likely to work again. Parents, teachers, and students can participate because there is no jargon and the conversation is focused on solutions. When participation such as this is achieved, individual team members share a collective ownership for the decisions being made.

Team Decision Making

Avoiding the unintentional blaming and shaming at planning meetings shapes the forum for decision making and offers everyone affected by the interventions voice, access, and ownership of the process. Interventions based on strengths and data gathered by the team determine educational decisions. The fundamental difference in team decision making versus traditional expert eligibility determinations is the degree to which team members contribute to the decision-making process. At the most basic level, school-based teams define the concern, probe for strengths, determine what needs to be done, evaluate the success or failure of each intervention, and decide what comes next based on information they all share. The team maintains focus on the student and the teacher's response to intervention efforts, as opposed to focusing on deficits within the student and the teacher. The school psychologist can help families and classroom teachers share necessary information by establishing the tone and openness to the planning process, which uses the strengths of the people who must carry out and evaluate the interventions.

BEST PRACTICES IN AREA

Shifting the focus from a dual system of decision making to a unified system considerably changes the school climate. Instead of expending valuable time and energy documenting student failure in general education, waiting for testing, and hoping for a categorical placement, teams expend their time and energy designing strength-based interventions and using the resulting data to drive team decisions. In a unified system, teams use the existing talents of teachers, students, and families in new ways. The team shifts the focus from eligibility determination to planning and judging the effectiveness of the intervention implementation and does not judge the implementers or the student. Family involvement becomes actively contributing information and making decisions with other team members instead of signing consent to test or placement forms. School-based team-driven problem solving engages the members and includes the members in determining effective strategies that will adequately address academic and/or behavioral concerns for individual children and their classroom teachers. As depicted in Figure 2, the process serves to provide formal and informal supports for any child within the educational system who is experiencing academic or behavior difficulties. To accomplish this, teams need to focus on more than individual student plans. For example, many schools in Kansas use Student Improvement Teams to (a) address the needs of individual students, (b) develop partnerships with families and local organizations (e.g., local mental health centers, family organizations, social services, businesses, law enforcement), and (c) develop policy and staff development recommendations and connect team efforts with school-based accountability controls (e.g., systems of accreditation, compliance monitoring).

Preparing families and teachers for their contributions during early problem-solving efforts around an individual student facilitates meaningful teacher and family involvement. Table 2 provides general problem-solving guidelines along with questions that shape strengths-based discussions.

The team collects information by examining personal experiences of people involved, record reviews, test information, interviews, and observations (Heartland Area Educational Agency, 1994; Sattler, 1988). Preparation includes meeting with the family in an informal, small setting to get to know the family and to help the family identify their strengths (the parents and their child), areas of concern, related factors, and to define interventions that have worked before or in the family's opinion are likely to work again. The same must be done with each classroom teacher.

1. What are the functional strengths of the child, family, and school? 2. What are the areas of concern? 3. What are contributing causes of the concern related to curriculum, instruction, environment, and the learner? 4. What do we think is the most likely contributing cause, and what can be done to make things better? 5. How will we know it is working?	1. What are your child's strengths? What does your child do best? What is your child most proud of? 2. What are the strengths of your family? Think about each person in your family individually as well as things you do as a family. 3. What do you see as strengths of your child's teacher and school? 4. In what area(s) could your child use the most improvement? What things does your child seem to struggle with the most? 5. When you think about the things your child needs to inprove, what could be possible causes that we could change in order to make things better? Think about the following areas: • Curriculum: For example, the curriculum materials brought home are difficult for your child to read; there are not many practice items for your child to completely understand what is being taught. • Instruction: For example, your child tells you he gets lost when the whole class is learning something; your child does not understand the things the teacher is teaching. • Environment: For example, your child has difficulty studying when there is lots of noise around; your child has difficulty following classroom routines. • Learner: For example, your child lacks good study skills or is very disorganized; your child does not seem to notice that he is doing his homework incorrectly. 6. What are things you think would help address the areas your child has difficulty with? In what ways does your child appear to learn best? Are there any arrangements that seem to work best? Are there certain things that motivate your child to learn or to participate?
Educational Decision Being Made: Entitlement Determination	
Evaluation questions	**Questions to facilitate meaningful family contributions**
Entitlement Component 1: Evidence of resistance to reasonable general education intervention efforts	
1. What appears to be effective or not effective with this student? 2. What do the data tell us about where to go next?	1. What changes have you noticed since we began implementing interventions to improve your child's performance in (area of concern)? 2. What things appeared to help or not to help? 3. What are your ideas about what could be tried next?
Entitlement Component 2: Evidence of a severe discrepancy from peers' performance levels in the area(s) of concern.	
3. What is the magnitude of the presenting problem? Discrepancy evident across both sources and agents of information.	4. In what ways does your child's difficulty in (insert area of concern) affect your child's education and functioning at home or in the community? 5. Is this a new area of concern, or did you have concerns in this area with your child last year?
Entitlement Component 3: A data-based description of the resources necessary to improve and maintain the individual's rate of learning at an acceptable level.	
4. Given the presenting concern and response to past interventions, what needs to be done to enable the child to participate and progress in the general education curriculum?	6. Based on your best thinking at this moment, what things could be done to help your child in (insert area of concern)? 7. What things do you think could be done at home to help your child in (insert area of concern)? What support would you need in order to make this happen?

Table 2. *(continued)*

Entitlement Component 4: Convergent evidence logically and empirically supporting the teams' decisions	
5. Is this a child with a disability as defined by IDEA or § 504? 6. Does this child need specially designed instruction to benefit from education?	8. Given your understanding of what a child with a disability is, does the information discussed with the rest of the team members fit with what you are seeing with your child?
Educational Decision Being Made: Instructional Planning	
Additional questions	**Questions to facilitate meaningful family contributions**
1. What are the measurable annual goals for this student?	1. What do you see your child doing for himself or herself in 1 year? In 3 years? After high school? 2. At the end of this year, what is one thing you want your child to be able to do that the child is not doing right now? 3. Do you have any nightmares you want to avoid? 4. If the program we come up with works, then what would you expect to see your child doing in class?

Methodically examining the strengths and resources of the student, teacher, and family provides voice during problem-solving efforts. In the team-centered approach delineated in Table 1, families and school personnel ensure that the resources of the team are identified and used when selecting interventions that are based on their likelihood to succeed. Implementing the intervention plan requires the team to set action items with responsibilities, time lines, and expected outcomes delineated in the plan. The team monitors the student's progress and reconvenes to assess the integrity of implementation and the adequacy of the student's response. When evaluating the adequacy of student progress, team members gather perceptions of progress from the teacher, family, and student and then examine the data specified in the plan. After considering all data, the team determines whether the intervention plan should continue or be changed. If progress is not sufficient, then the interventions are modified. The team maintains its focus on solving the presenting problem. The team continually monitors to assure that the interventions fully utilize the learning/teaching strengths of the student and the teacher. When strengths-focused interventions fail to afford the student benefit from general education, or if the interventions are producing gains but require extremely high levels of support, the team may recommend an initial evaluation for special education.

Problem-Solving Efforts During an Initial Evaluation

When the school-based team initiates an initial evaluation, the team reconfigures to include those necessary to determine if the child is a child with a disability who needs special education. The end result is always the development of a plan to address the individualized needs of the child, regardless of the eligibility decision. The school psychologist's role is to help the extended team understand special education eligibility issues as they contribute to the evaluation and to participate in the eligibility decision. The school psychologist, to prepare families to be meaningful participants in eligibility decisions, must explain to the families the guiding criteria around which data will be collected. Table 2 includes questions to facilitate family and classroom teacher involvement during this process. The entitlement components described by Tilly, Reschly, and Grimes (1998) offer a structure for considering eligibility and need for special education. Basically, the components require the extended building team to use the data from their early problem-solving efforts when determining what additional information is needed to make eligibility judgments. During the special education eligibility meeting, all team members discuss data relevant to each of the eligibility components. The school psychologist assures that each team member is an active contributor in the discussion and facilitates the team's discussion to answer the questions of eligibility and need for special education services. Finally, building team members determine what needs to be done to enable the child to progress in the general education curriculum. With this model, the team building is poised to write the individualized plan for the child, even if the child is not found as eligible for special education. They retain ownership of the process and the plan.

Problem-Solving Efforts During Instructional Planning

With classroom teachers and families involved in every phase of educational decision making, instructional planning simply progresses. The school-based team writes an education plan for the student (i.e., Individualized Education Program, §504 Plan, or Student Improvement Plan) and sets measurable annual goals for the student. Team members review the initial evaluation information from a strengths perspective, determine present levels of educational performance, identify the resources needed to address the student's needs, and determine how progress will be monitored so the plan can be evaluated. Table 2 concludes with questions to assist family members and the team to determine annual goals.

SUMMARY

Several states have moved practices toward a functional and non-categorical identification process and service delivery model by using the problem-solving model as the foundation (Ysseldyke & Marson, 1998). Family involvement in a school's problem-solving process means that families are included as equal and integral members of the school team. As members of the school team, families participate in the design, implementation, and evaluation of services. School psychologists play an integral role in reconceptualizing strengths-based, data-driven assessment processes and family involvement. As outside experts, school psychologists can help schools shift the focus from a categorically driven model to one of team-centered and strength-based practices. Developing a team-centered approach allows the school psychologist to ensure families are at the table when the process is defined, are brought into the process early when a concern is noticed, and have a voice that is valued and honored as they contribute to the decisions made about their child.

When families are informed and provided with ways to be team members, they can meaningfully participate in educational decision making. When school-based teams become a way of doing business that values each member's contributions, seek an understanding of team strengths, and create a process in which educational decision making is truly about what is best for the child, we will realize the capacity that resides in each of our schools to care for its members.

ANNOTATED BIBLIOGRAPHY

Reschly, D. J., Tilly, W. D., & Grimes, J. P. (Eds.). (1998). *Functional and non-categorical identification and intervention in special education.* Des Moines, IA: Iowa Department of Education.

This collection offers a thought-provoking look at how the special education decision-making process is being changed to better serve children and families. The impressive collection of scholars contributing to this book brings a common focus on problem solving to each chapter. The book covers systemic issues, legal parameters, and non-categorical approaches for the range of disability areas and includes chapters on early childhood, transition, and low incidence populations. This book should be a must read for today's educator.

AUTHOR NOTES

28 Best Practices in Supporting Home-School Collaboration

Amy N. Esler, Yvonne Godber, and
Sandra L. Christenson
University of Minnesota

> *School-family partnerships are the mutual collaboration, support, and participation of parents and school staff at home or at the school site in activities and efforts that directly and positively affect the educational progress of children.*
>
> Moles and D'Angelo (1993, p. 214)

OVERVIEW

Over the past decade, a number of studies has added to our understanding of the benefits of home-school collaboration efforts, and specifically to how schools can reach out and partner with all families. Having captured the interest of numerous educators, educational researchers, and policy makers, many have begun to clarify not only the *outcomes* associated with families and schools working together to support student learning, but also the *processes* for encouraging effective, positive interactions between families and schools. This shared interest stems from the belief that to maximize the impact of prevention and intervention efforts, all contexts in which children develop need to be addressed. Home-school collaboration, which is defined as establishing and maintaining productive, working relationships between families and schools to facilitate children's learning, is one manifestation of the knowledge that children's academic and social growth occurs across multiple settings.

Current concerns for youth have prompted calls for increased family participation in education. As schools have begun opening their doors for more meaningful family participation, many of the more traditional family involvement practices have proved insufficient, and new and varied methods have been recommended. Although change is rarely easy, at the same time new opportunities for school psychologists and others interested in supporting students by enhancing the relationship between families and schools now exist. In this chapter, the historical and political context surrounding the vast, continuously growing home-school collaboration literature is briefly summarized before key features and barriers facing such collaborative efforts are presented. Next, a model depicting the critical processes necessary for enhancing connections between home and school reveals how attitudes, relationships, and actions influence the manner in which families and educators are able to collaborate successfully.

BACKGROUND

Whether called home-school collaboration, parent/family involvement, or family-school partnerships, the goal of promoting strong bonds between families and educators is to enhance learning for all students. To encourage and support student learning, it is important to heighten opportunities for families to participate in meaningful ways with their children's education. The recent priority aimed at enhancing relationships between home and school rests soundly on the theoretical underpinnings proposed and described by Bronfenbrenner (1979), Coleman (1987), and Pianta and Walsh (1996). These individuals, among others, conceptualize how children's development occurs across home, school, and community settings. Just as learning does not stop when children leave the school building at the end of the day, home influences cannot be separated from children at the beginning of the school day. Both school and home reciprocally influence and help determine the path children's development takes. Home-school collaboration reflects the critical interface these two vital, socializing systems have on children's learning. The focus of home-school collaboration becomes one of building and enhancing connections between these systems to support and maximize the learning potential of children.

Efforts by educators to increase family-school partnerships stem from a variety of cultural, sociological, and policy-related changes over the years. Increasing numbers of women obtaining college degrees and joining the workforce, increased mobility as people find new jobs, and higher divorce rates have affected the manner in which children are educated and raised. Day care needs, issues related to moving, financial stressors of single parents, increased social isolation owing to weakened social support networks, and lessened time, support, and supervision for children made it apparent that the traditional manner in which families and schools interacted was insufficient. Limiting and prescribing roles for families no longer suffices in preventing and solving children's school-related problems.

Over time, researchers and practitioners have grown increasingly interested in ascertaining which aspects of a child's "world" are most likely to encourage successful outcomes in school and in life. Most of the data found in over 200 journal articles existing in this literature database are correlational in nature. Nonetheless, the numerous findings can be aggregated to show that parent involvement does indeed positively and significantly influence academic outcomes for students (Henderson & Berla, 1994). Valuing, supporting, and welcoming families' efforts to support their children's learning has been associated with a variety of indicators of successful student performance. These include higher academic achievement (e.g., test scores, grades), higher rates of school engagement and attendance, reduced behavior problems in classrooms, fewer suspensions, and lower dropout rates. It has grown increasingly apparent that the more families and schools are able to collaborate, the more likely benefits are noticed for not only students, but also their families and schools. Several benefits noted by Epstein (1995) are summarized in Table 1.

Until recently, the primary focus of family involvement research was identifying the effects of family or home environmental conditions on student perfor-

Table 1. Benefits of home-school collaboration for students, families, and schools

For students

- More positive attitudes toward school
- Higher achievement in reading
- Higher quality and more grade-appropriate homework
- Completion of more homework on weekends
- Observing more similarities between family and schools.

For parents

- Receiving ideas from school on how to help their children
- Learning more about educational programs and how the school works
- Becoming more supportive of children
- Becoming more confident about ways to help children learn
- Gaining more positive views of teachers and the school

For Teachers and schools

- Improved teacher morale
- Higher ratings of teachers by parents
- Teachers' rating of parents as more helpful
- Improved student achievement
- Parents support schools and bond issues

394

mance. Much less research focused on the effect of the *transactions* between home and school. In contrast, current work is based on systems theory and consequently is directed more specifically at understanding the effect of the interface of family and school on children's performance. This chapter, which serves as an extension of the original chapter by Christenson (1995a), continues to underscore an emphasis on the importance of building trust with families, maintaining collaborative relationships, and using a problem-solving approach to facilitate constructive partnerships between families and educators. Perhaps the most profound change in the last 5 years is the immense support and attention these points have received. Recent legislative policies specifically direct schools to forge partnerships with families as part of school reform initiatives. National and state agencies and organizations now actively promote family and community involvement through standards of recommended goals, practices, materials, and funding. For example,

1. Title 1, Elementary and Secondary Education Act of 1965 as amended by Improving America's Schools' Act of 1994 (P.L. 103[illegible] 382) requires states and school districts to include parental input at the local school level.

2. Parent Participation, Goal 8 of the National Education Goals Panel (1998) (http://www.negp.gov/page 3-1) states: "By the year 2000, every school will promote partnerships that will increase parental involvement and participation in promoting the social, emotional, and academic growth of children." The goal's three objectives are informative for practice:
   - Every state will develop policies to assist local schools and local educational agencies to establish programs for increasing partnerships that respond to the varying needs of parents and the home, including parents of children who are disadvantaged or bilingual, or parents of children with disabilities.
   - Every school will actively engage parents and families in a partnership that supports the academic work of children at home and shared educational decision making at school.
   - Parents and families will help to ensure that schools are adequately supported and will hold schools and teachers to high standards of accountability.

3. National Standards for Family Involvement Programs (National P. T. A., 1997) are intended to promote meaningful parent and family participation, raise awareness regarding the components of effective programs, and provide guidelines for schools wishing to improve their programs.

4. The U.S. Department of Education (1997) issued a framework for developing contracts with all members of a school community (including parents) in which the necessity of a shared responsibility for student learning is emphasized.

As a result, many school districts have developed district guidelines for promoting family involvement in education (Rutherford, 1995). For example, in 1996 Minneapolis Public School District adopted official family involvement standards that guide implementation of programs across the 78 schools (Minneapolis Public Schools, 2000).

Although school personnel are beginning to realize and talk about the importance of partnering with families, many are unsure of how to go about doing it in a welcoming, empowering way and are often frustrated with parents not participating in the activities they have designed for them. Schools tend to talk the talk of family involvement; they do not yet necessarily walk the walk. Too often schools set the agenda despite the collaboration rhetoric (Swap, 1993). Yet evidence exists that parents (Christenson, Hurley, Sheridan & Fenstermacher, 1997), teachers, and students (Metropolitan Life Survey, 1998) desire a more proactive role for families in home-school partnerships. Given the historical and cultural roles of families and teachers in schools, it has been recommended that schools must take the responsibility for reducing barriers to family involvement and be the first to reach out to parents in innovative, nontraditional ways (Davies, 1993).

Others have questioned the degree to which families share equal power with educators, particularly in decision-making situations (Weiss & Edwards, 1992; Harry, 1992). Educators may feel threatened about losing control, power, and prestige over educating children by relinquishing too much decision-making authority to families (Edwards, 1992). Also, families are used to being blamed for their children's failure in school and being told what to do by schools. Moving toward an emphasis on including all families, educators are encouraged to be the first party to reach out to ask families to share their guidance and knowledge of their children. While current actions may not necessarily reflect the belief in the importance of shared responsibility for student outcomes, the orientation is clearly continuing to move toward an emphasis on the value of partnering with all families.

In general, there is agreement that parents should be involved in schools, despite the fact that home-school collaboration is a multi-dimensional concept that remains ill defined, and school personnel are not necessarily sure of how to welcome all families as partners. In this chapter, we support the concept of family and schools as partners proposed by Christenson and Sheridan (2001). As can be seen in Table 2, home-school collaboration, when defined as partnering, is a philosophy and way of thinking about sharing information and resources to foster positive school and learning experiences for children and youth.

The challenge for school psychologists and other school personnel is to facilitate the development of an environment that exudes the core belief that schools cannot fulfill their mission of successfully educating all children if families are excluded from the process. Collaborating with families has to be much more than an activity—it must be a pervasive attitude. Home-school collaboration is dependent upon a school's responsiveness to family needs by empowering parents to share in the decision making that is likely to affect the way schools currently work. In the following section, basic considerations for establishing productive, positive, and central relationships with families are presented.

BASIC CONSIDERATIONS

Key Points for Effective Home-School Collaboration

Home-school collaboration is a preventive, problem-solving approach focused on supporting learners. The primary reason for families and schools to collaborate is to support the growth and development of students academically, behaviorally, and socially. Therefore, the goal of collaboration is student-focused, not simply family-involvement focused. Although the focus is on joining forces to facilitate children's success in school, benefits are also noted for families and schools in the process of collaborating to prevent problems and help children succeed. For example, optimizing the family-school relationship has been shown to be a protective factor for students and families "at-risk" (Weissberg & Greenberg, 1998).

As in any relationship, outcomes are more effective, and riddled with fewer barriers, when the basis for convening is to achieve a shared goal rather than to solve a problem. However, as families and school personnel often only interact when problems arise, the need for a solution-oriented, problem-solving approach is essential. Indeed, the extent to which families and schools come together to effectively solve pending crises can encourage or discourage future attempts to interact and collaborate on the part of both educators and families. In discussing how effective connections are made between families and schools, Christenson and Godber (2001) state:

Table 2. Defining features for family and school as partners

- A ***student-focused philosophy*** wherein educators and families cooperate, coordinate, and collaborate to enhance learning opportunities, educational progress, and school success for students in four domains: academic, social, emotional, and behavioral.
- A belief in shared responsibility for educating and socializing children: both families and educators are *essential* and provide resources for children's learning and progress in school. There are no prescribed roles or activities for families or educators; rather, options for active, realistic participation are created.
- An emphasis on the quality of the interface and ongoing connection between families and schools. Creating a constructive ***relationship*** (how families and educators work together in meaningful ways) to execute their respective roles in promoting the academic and social development of children and youth is most important.
- A ***preventive, solution-oriented*** focus, one where families and educators strive to create conditions that facilitate student learning, engagement, and development.

Source: Christenson and Sheridan (2001).

> The focus is on creating a collaborative ethic, which refers to a fundamental way for families and schools to work together in which (1) the relationship or interface between families and schools is emphasized over the specific role either should or could assume, and (2) problem solving provides a systematic, structured way of creating mutual support for interventions and activities that improve the educational experience for students, engage students as learners, or orient them to a more positive trajectory for development (p. 456).

Home-school collaboration reflects the belief that both families and educators are critical for socializing learners. More than ever, schools and teachers today need to work together and support each other's efforts for children and youth to thrive. Reaching this goal requires an appreciation of the numerous ways both educators *and* families support children's learning. Bempechat (1998) raises interesting questions on how adults socialize children and youth to be learners, and how children perceive learning as a worthwhile endeavor. Also, based on an extensive review of the literature, Christenson and Peterson (1998) identified six factors (i.e., practices) that families, schools, *and* communities employ to create conditions that positively influence varied indicators of students' school performance. These factors are presented in Table 3. While families and educators contribute to student learning in different ways, their roles are both equally important and necessary for fostering students' belief in the importance of learning and the value of school. Consistent messages between home and school have been shown to reduce barriers facing students, particularly when cultural or ethnic differences exist (Phelan, Yu, & Davidson, 1994).

To accomplish this consistency, both families and schools must understand their overlapping roles and responsibilities in making the collaborative relationship successful (Epstein, 1995). While the role of teachers for children's education is well established, the critical role played by parents is often underestimated. Yet there are countless ways families influence their children's learning (see Christenson, Rounds, & Gorney, 1992). Moles and D'Angelo (1993) assert that the underlying philosophy when collaborating with families must be: "Every family functions as a home learning environment, regardless of its structure, economic level or ethnic or cultural background. Consequently, every family has the potential to support and improve the academic achievement of its children" (p. 30). Home-school collaboration efforts need to encompass practices and beliefs that make families feel respected, empowered, and consulted for their knowledge and expertise of their children.

Home-school collaboration requires broad, meaningful opportunities for parent participation. A common perception of what parent involvement entails tends to be limited to activities designed for families by school personnel; for example, volunteering in the classroom, making copies, helping children with their homework, or serving as chaperones for field trips.

Table 3. Six factors encouraging children's learning

Practice	*Definition*
Standards and expectations	The level of expected performance held by key adults in children's lives.
Structure	The overall routine and monitoring provided by key adults for youth.
Opportunity to learn	The variety of learning options available to youth in the home, at school, and within the community.
Support	The guidance provided by, the communication between, and the interest shown by adults to promote student progress in school.
Climate/relationships	The amount of warmth and friendliness, praise and recognition, and the degree to which the adult-youth relationship is positive and respectful.
Modeling	How adults demonstrate desired behaviors and commitment/value toward learning and working hard in their daily lives.

Source: Christenson and Peterson (1998).

While parents want to be involved with their children's education, they may not view these preconceived roles as allowing for as broad, or meaningful, participation as they would prefer (Harry, 1992). In a study sponsored by the National Association of School Psychologists (NASP), Christenson et al. (1997) found that parents desired more parent involvement activities than schools found feasible to provide. Parents ranked 33 family involvement activities in order of preference, and school psychologists ranked them in order of feasibility. Although significant overlap existed, parents' mean ratings were higher than those of school psychologists in 94% of the cases. The authors concluded that "the goal in planning involvement programs is to achieve a match between what parents want (would use) and what schools perceive as feasible for supporting student performance. This match can best be achieved with parent-educator input and reciprocity in planning" (p. 127).

A change in parent-professional discourse has been recommended to allow opportunities for parents to be true *co-teachers* who share important, decision-making power with school personnel at all levels in the functioning of the school (Comer, Haynes, Joyner, & Ben-Avie, 1996). Effective collaboration with families creates avenues for parents to pursue initiatives that may not stem from educators, but that are still viewed by parents as critical in fostering a positive learning environment. Based on the family-school partnership work of Epstein and others, the National Standards for Parent/Family Involvement Programs developed by the National P. T. A. (1997) reflect the need to broaden traditional conceptions of family involvement. Combined with quality indicators and sample applications, the six national standards follow:

1. Communicating: Communication between home and school is regular, two-way, and meaningful.

2. Parenting: Parenting skills are promoted and supported.

3. Student learning: Parents play an integral role in assisting student learning.

4. Volunteering: Parents are welcome in the school, and their support and assistance are sought.

5. School decision making and advocacy: Parents are full partners in the decisions that affect children and families.

6. Collaborating with community: Community resources are used to strengthen schools, families, and student learning.

Similarly, in a handbook published by the U.S. Department of Education (1997) a commitment to engaging families, educators, and communities by outlining the shared responsibility necessary for student learning is shown. According to the *Compact for Learning: An Action Handbook for School-Family-Community Partnerships*, all members of a school community are responsible for holding high standards for students, enhancing home-school communication, and facilitating the development of strong family-school partnerships. If school psychologists and other educators limit their view of families to traditional, preconceived roles, then a myriad of potential opportunities for building relationships with families—across home, school, and community settings—may be lost. Clearly, best practices in home-school collaboration require a redefinition of what constitutes parent involvement.

Building relationships for effective home-school collaboration takes time, effort, and leadership. There is no single approach or model that will work with all families. Building positive, sustainable relationships between educators and families for the purpose of supporting student growth and performance takes time and effort and requires leadership that facilitates and fosters these efforts. A truly flexible, collaborative approach affords a broad range of roles and responsibilities for families working together with educators, yet is in tune with the desires and wishes of members of each unique school community. Both quantity and quality make a difference in how successful schools are when they reach out to invite and include parent participation. Seeley (1989) claims that schools that have experienced success in engaging families do many of the same things as other schools have attempted but that "the difference is that these schools do more of these things, more persistently, because they are now operating on a different model of schooling—a model in which parent involvement is a necessity and the school is seen as a collaborative community learning center" (p. 47). Patrikakou and Weissberg (1999) found the quality of family-school interactions and the degree to which parents perceive teacher outreach efforts as welcoming were important determinants in how, when, and if families became involved with their children's schools.

Home-school collaboration efforts must be considered a priority, permeating all school actions, if benefits are to be accrued (Comer et al., 1996). These efforts reflect the importance of collaborating with families to influence interactions and, consequently, are not viewed as yet another "program" the school offers (e.g., "the family involvement coordinator takes care of that"). It must be recognized that the process of developing such relationships takes time, typically requiring a minimum of 3–5 years for an impact to be noted (Epstein, 1995), and would have implications for our assessment and intervention practices, particularly in terms of co-roles for families and educators.

Barriers and Challenges

It is true that benefits for students, families, and schools exist when home-school collaboration is taken seriously. It is also true that the road getting there is wrought with numerous interpersonal, logistical, and systems-level barriers. The categorization of barriers by Liontos (1992) (see Table 4) is useful because it highlights attitudinal and logistical barriers for parents, teachers, and schools. Collectively, the barriers for families and educators reveal the challenges facing home-school collaboration. An important beginning is to recognize that barriers exist for both partners in the relationship.

Logistical barriers facing families include lack of time due to several jobs, single parenting, transportation issues, lack of day care options, and scheduling conflicts. Attitudinal barriers, such as feelings of inferiority, alienation, or hostility toward educators as a result of their personal negative experience in school, grow as miscommunications and misunderstandings arise about how schools work, the resources schools provide, and how they can assist their children's success in school. Furthermore, Hoover-Dempsey and Sandler (1997) have proposed that parental self efficacy, construction of the parental role, and the messages and invitations presented to parents influence parents' abilities either to initiate, or to be receptive to, interactions with school staff.

Logistical barriers facing educators relate to lack of time, training, and administrative support. Time factors are frequently a result of increased responsibilities for teachers, often in conjunction with the

Table 4. Barriers and misunderstandings

Barriers for parents

- Feelings of inadequacy, failure, and poor self-worth
- Negative attitudes or bad experiences with schools
- Suspicion or anger that schools are not treating them equally
- Leave it to the schools
- Cultural and language barriers
- Economic, emotional, or time constraints
- Logistical problems: child care, transportation, scheduling

Barriers for schools and teachers

- Commitment to parent involvement
- Confusion about the role of teachers
- Concerns about turf and territory
- Doubts about their abilities to work with at-risk parents
- A belief that at-risk parents do not care and will not keep commitments
- Low teacher expectations for at-risk children
- Schools assume a passive role or fail to help parents feel welcome
- Communication from schools focuses on the negative
- Dwelling on the hard-to-reach concept
- Lack of time and funding

Source: Liontos (1992).

increasing demands for children in their classrooms. Teachers have rarely taken courses during teacher preparation or engaged in ongoing professional development activities to work with families *as partners* (Morris & Taylor, 1998). Weak administrative support for teachers' time and effort in reaching out to families can squelch future proactive, teacher-initiated, home-school collaboration activities. Attitudinal barriers for teachers and educators include misconceptions about the ways families support children's learning, fear of reaching out to families due to cultural or linguistic differences, stereotypes about poor, minority families, and/or pitying families for their situations and therefore holding lower expectations for children's performance. Furthermore, incomplete knowledge about and experience with different cultures and lifestyles may lead teachers to avoid contact with families, thereby perpetuating the perception of parental apathy and lack of support for classroom efforts (Thorp, 1997).

Barriers must be identified, acknowledged, understood, and systematically removed. Conceptualizing barriers for families and schools differs from examining *why* families choose not to be involved—it requires school personnel to examine their current school practices for including families. Barriers often can be reframed as challenges for parents, educators, and the partnership, all needing time for the stakeholders to engage in ongoing dialogue and problem solving about children's needs. Families need repeated, positive opportunities to share their thoughts, desires, expertise, and expectations; and teachers need time, support, and training to work effectively with families. Despite the requirements for time, dedication, and leadership (and complexities of these), many situations can be improved or ameliorated when teams of parents and educators work together to proactively address concerns.

School Psychologists as Change Agents

Changing the way educators and parents think about home-school collaboration is a big task, often involving changing the way schools do business. However, the benefits to be gained are many and far-reaching. Although it is a process that often is accompanied with challenges, the rewards and subsequent opportunities can be observed in the academic, social, and behavioral progress and performance of students. School psychologists can work to obtain these benefits by acting as change agents.

In her call for school psychologists to accept leadership roles for enhancing family-school partnerships, Epstein (1992) claimed we are in an ideal position to facilitate initiatives surrounding planning, implementing, and evaluating strategies for building constructive relationships between home and school. Many of our roles fit naturally into these initiatives. First, school psychologists have a working knowledge of current research on outcomes related to home-school collaboration, as well as on effective strategies for collaborating. Given this knowledge, they are in a strong position for disseminating information to administrators, teachers, and families and advocating for change at the systems level. Second, school psychologists work with teachers and families regularly, giving them the opportunity to put collaborative practices into action. Some examples include (a) setting the tone for parent-educator meetings to ensure that families' ideas, views, and support are solicited; (b) changing the way parents are invited and informed about meetings to reduce barriers to their attendance; and (c) consulting with teachers to develop efficient, effective ways to communicate positive information to parents about their children regularly. Finally, school psychologists' training in program evaluation can be utilized to assess how well collaboration efforts are being implemented, and how well they are working to increase family involvement and student achievement.

BEST PRACTICES

Attitudes, Relationships, and Actions: A Framework for Home-School Collaboration

The goal of best practices in home-school collaboration is to work as partners to support children's learning. Thinking of family and school as "partners" does not refer to a specific model or approach. Rather, it refers to a mutual effort toward a shared goal, and as a result implies shared responsibility of families and educators for supporting students as learners (Christenson & Sheridan, 2001).

We contend three components, Attitudes, Relationships, and Actions, are essential to creating positive home-school collaboration to enhance students' learning and schooling experiences. The components, which are theoretically driven or scientifically based, are

1. Attitudes: The values and perceptions held about family-school relationships.
2. Relationships: The quality of interface and type of family-educator interactions.
3. Actions: Strategies for building shared responsibility and the partnership.

As shown in Figure 1, attitudes, relationships, and actions mutually reinforce one another. In this conceptualization, attitudes held by school staff set the stage for the relationships that are developed with families and the kinds of actions carried out to support children's learning. Relationships are relevant, because their quality often is the factor that makes or breaks the efforts of educators to address an individual- or systems-level problem. Finally, actions are *what* schools and families do to form partnerships. Actions refer to behaviors; that is, how schools join with families and how schools and families work together to support children's learning, both at home and at school. In this section, considerations for how school psychologists can facilitate effective attitudes, relationships, and actions for promoting home-school collaboration are described.

ATTITUDES

Working as partners is an attitude—not solely an activity to be implemented. Although both parents' and educators' attitudes are integral to forming productive relationships, researchers have shown that educators' attitudes are critical to the success of partnerships. For example, how schools reach out to families was determined by Dauber and Epstein (1993) to be more important determinants of parent participation in education than were parents' educational, socioeconomic, or ethnic backgrounds.

Attitudes that foster home-school partnerships. Attitudes set the context for *how,* and even *whether,* schools and families work together. A major program of research by Epstein and Dauber has consistently produced evidence that patterns of teacher attitudes are an important factor in parental decisions about participation. Parents who interacted with teachers who held positive attitudes about partnerships and expressed interest in parent involvement were more positive about school, more involved in the school, and expressed stronger beliefs in the "goodness" of school than parents who interacted with teachers who placed a low priority on family-school partnerships (Dauber & Epstein, 1993). Illustrations of three essential school-based attitudes are presented in Table 5. This list is not exhaustive and can be expanded to fit the particular needs and situations of a school community.

Table 5. Attitudes that foster family-school partnerships

Shared responsibility

- Home-school collaboration results in a shared responsibility among parents and educators for educational outcomes (Christenson, 1995b).
- Posture of reciprocity: With the provision of official channels for reciprocal rather than one-way discourse between educators and families, educators can begin the process of developing collaborative practice (Harry, 1992).

Parents are experts

- Parents' knowledge, expertise, and resources are valued as essential to children's success (Ooms & Hara, 1991).
- The message that both parents and teachers have important knowledge and skills to impart to students is consciously communicated at school (Raffaele & Knoff, 1999).

Preventive, solution-oriented focus

- The school recognizes its responsibility to forge a partnership with all families in the schools, not simply those most easily available (Ooms & Hara, 1991).
- The importance of seeking parents' views and expertise is promoted in developing policies and solving school-wide problems; with some schools giving parents important decision-making responsibilities at a policy level (Ooms & Hara, 1991).

Shared responsibility. A key attitude that facilitates family-school partnerships is that educating and socializing children is a *shared responsibility*—both families and educators are considered *essential* and providers of resources for children's learning and progress in school. Supported by the recognition that children perform better when in and out-of-school time is used constructively (Christenson & Peterson, 1998; Entwisle, Alexander, & Olson, 1997), shared responsibility is the cornerstone of the NASP position statement on home-school collaboration (www.naspweb.org/information/pospaper_hsc.html).

Parents are experts on their children. Once children are school-age, they spend approximately 75 percent of their waking hours outside of school (Clark, 1993). Parents hold valuable information about their children's developmental history, likes and dislikes, and learning style. This information is vital to understanding the many contexts of children's lives to design interventions and plan evaluations. Furthermore, all parents are involved (directly or indirectly) in their children's learning. All parents are their children's teachers, from setting expectations for their children's learning to providing direct help and support with schoolwork. Parent involvement in education does not only happen in school buildings.

A preventive, solution-oriented focus. This attitude values the efforts of families and educators for creating conditions that facilitate student learning, engagement, and development. As part of this focus, educators recognize that all parents have strengths that can be utilized to address both individual and systems-level concerns. Educators also recognize that problems (academic, behavioral, social) are best solved through coordinated efforts among home, school, and community. Consultation that involves parents, students, and educators in teaming to solve learning and behavior problems has been linked to decreased referrals for testing and improved teacher perceptions of students with learning or behavior difficulties (Fuchs, Fuchs, & Bahr, 1990) as well as improvement in academic, social, and behavioral performance (Sheridan, 1997). Effective solutions require non-blaming interactions (Weiss & Edwards, 1992) and often require consistent messages and behaviors across multiple settings (see Reid & Patterson, 1996).

A role for school psychologists. Two relevant questions to be answered with respect to the proposed attitudes seem to be

1. At my school, how would the belief system about the relationship between parents and educators with respect to children's school performance be characterized?
2. In what ways do key stakeholders believe in shared responsibility between home and school?

Belief in shared responsibility is consistent with the literature on empowering families to be active partners in their children's learning. Parents are not empowered as partners when educators hold attitudes that suggest parents are not competent to support their children's learning and/or prevent or address learning problems. Defining empowerment as removing barriers to provide equal opportunity (e.g., opportunity for parents who experienced negative school experiences to learn about school policies and practices), Cochran and Dean (1991) described three stages of empowerment: (a) improving parents' self-efficacy, (b) building a relationship between the parent and at least one school staff person, and (c) social action—parents' actual involvement in decision making. Should the belief in shared responsibility and empowering families for educational outcomes not be present, school psychologists may want to conduct inservice training on the empirical basis for shared roles and responsibilities (e.g., Christenson & Peterson, 1998) and parents' roles in the socialization of learners (Bempechat, 1998; Scott-Jones, 1995). This would provide opportunities for dialogue about this content.

RELATIONSHIPS

Positive attitudes toward families and about the benefits of an effective family-school relationship for children's performance in school are a pre-requisite for initiating and maintaining family-school relationships. These relationships are conducive to school success. In their family-school collaboration project in New York City, Weiss and Edwards (1992) found that creating constructive *relationships* (the quality of the interface and ongoing connection between families and schools) to execute schools' and families' respective roles and responsibilities over time is more important than solving the immediate presenting concern for students at a family-school meeting.

Trust, an important factor in building relationships, is built through multiple interactions in which parents and school personnel respond to each other's needs consistently. The goal is for families to trust that educators are working in their children's best interests, for educators to trust that families are working in their children's best interests, and that they will jointly plan and share decisions about supporting students' educational progress. Unfortunately, trust between families and schools does not always progress to this level (Adams & Christenson, 1998).

Trust in the family-school relationship has tangible benefits for children. When families and educators trust each other to work collaboratively to support children's learning, parents participate more frequently in family involvement activities (e.g., parent-teacher conferences, open houses) (Adams & Christenson, 1998). Furthermore, Adams and Christenson (2000) have shown that trust has a small but significant positive relationship with students' grades and credits obtained toward high school graduation. They also found that the quality of the relationship is a significant predictor of parent and teacher trust.

How to build relationships. Because of families' and schools' particular needs and histories, attempts to connect with families require a tailored approach. The following practices are important components for school psychologists to consider when building relationships.

1. Family-centered practices: In research and practice, early intervention programs tend to involve families as integral partners in their children's learning and behavior development. There has been a call for continuing these practices in kindergarten and across school years (Pianta & Walsh, 1996). Relationships with families, especially those less connected to the schooling process, may benefit from applying strategies implemented in early intervention programs, including a set of strategies referred to as family-centered practices. Family-centered practices involve a *family orientation*, in which the interest is in the whole family rather than just the child; *positiveness*, which is thinking the best about families without passing judgment; *sensitivity*, which involves empathizing with families and understanding their needs and concerns; and *friendliness*, or treating families as friends (McWilliam, Maxwell, & Sloper, 1999). A study by McWilliam, Maxwell, and Sloper found that special educators, regular educators, and families of children with and without disabilities desired more family-centered practices than currently provided or received in schools.

2. Develop trust: Trust does not occur accidentally or coincidentally; rather, it develops as educators engage in certain actions that actively promote trust. According to Margolis and Brannigan

(1990), such behaviors include (a) accepting parents as they are; (b) sharing information and resources; (c) focusing on parents' aspirations, concerns, and needs; (d) keeping their word; (e) discussing objectives openly; and (f) preparing for meetings. Also important are focusing on the interactive process with parents, using structured problem solving approaches, and listening empathically. Findings from Adams and Christenson (1998) suggested that we also (a) create opportunities to build personal relationships with families, (b) create opportunities to be co-learners with parents, (c) engage in shared governance with parents, (d) develop effective conflict management strategies, and (e) maintain a focus on student outcomes.

3. Equal partners: Schools often are seen as unapproachable, professional institutions, and parents often feel powerless in confronting educators when conflicts arise. When educators give up some of their "professionalism" and acknowledge parental expertise about their children and contributions to their education, some of parents' fears may be overcome, and an equal partnership can develop (Gareau & Sawatzky, 1995).

4. Respect for cultural diversity: Schools and homes representing two different worlds is a recurrent theme in the family involvement literature (Delgado-Gaitan, 1991; Gareau & Sawatzky, 1995; Liontos, 1992). There is not a common understanding across cultures of the purpose of education, nor an understanding of how parents from different cultural backgrounds perceive their role or that desired by school personnel (Bempechat, 1998). Schools are continually challenged to develop an understanding of the social, cultural, historical, and linguistic achievements of different cultures (Delgado-Gaitan, 1991; Liontos, 1992; Swap, 1993). Creating a school environment that is an extension of the many cultures and communities it contains can enhance effective collaboration and increase opportunities for it to occur.

5. Personal connections: Informal opportunities for interaction between families and educators are important to developing caring, trusting relationships. Gareau and Sawatzky (1995) found that contacts, such as calling parents to share some of the positive things their children have done at school, establishing a relationship on a first-name basis, and making face-to-face contact whenever possible, helped them to build personal connections with one another. We need to know parents have some trust and positive contact with educators before trying to address critical issues for students. Davies (1990; cited in Swap, 1993) refers to these contacts as "essential lubrication" for more serious intervention.

6. Welcoming climate: Many authors argue that schools need to work harder to make families feel welcome (Liontos, 1992; McWilliam et al., 1999). To be successful at attracting parent participation, schools need to make families feel welcome. A cheerful physical environment, holding social events such as open houses or family "make and take" nights, and creating a family resource center with literature, videotapes, and audiotapes for parents to check out are some of the ways to make schools more comfortable and welcoming (Tomlinson, 1996).

ACTIONS

The language of shared responsibility. Before engaging in specific actions in home-school collaboration, attention to the language used in reaching out to families is highly relevant. Often, schools believe in shared responsibility and try to involve parents in important decisions about their child or about the school as a whole, but they still have a high number of "uninvolved" families. We need to communicate with families so we are *inclusive, solutions-oriented*, and *optimistic* about children's performance and future (de Shazer, 1988). These principles will help families to feel important as partners with schools and will give them hope for creating optimal learning environments and addressing shared concerns.

Inclusive language means keeping parents informed, creating opportunities for exchange of information, and using non-blaming language. There are no problematic individuals (parents, teachers, or students), only a problematic situation that requires the attention of the student, home, and school—all for the benefit of the student. Being solution-oriented involves emphasizing solutions, not problems, and emphasizing student progress and improvement toward goals. Optimistic language involves keeping the focus on what the student needs for the best school experience, having an optimistic view of children's development, and believing in parents' abilities (de Shazer, 1988). These principles are infused throughout school psychologists' actions for home-school collaboration.

Actions represent how educators and families interact to create shared responsibility for student learning; hence, they provide opportunities to address student learning directly. Drawing on the work of many researchers and educators, we present specific examples of practices in Table 6.

Table 6. Best practices for home-school collaboration: Actions and sample applications

Communication (Christenson & Hirsch, 1998)

- Strive to maintain a positive orientation: Good news phone calls, invite and incorporate parent reactions to policies and practices, contact parents at the first sign of a concern, reframe language from problems to goals for students.
- Develop and publicize regular, reliable, varied two-way communication systems: System-wide family-school communication/assignment notebooks, telephone tree, Thursday folders and newsletters, and shared parent-educator contacts.
- Keep the focus of communication on children's performance: Use electronic technology; bi-directional communications regarding classroom activities, progress, suggested activities for parents (Ames, 1993); home-school notebooks/notes; family-school meetings with students present; shared parent-educator monitoring system (e.g., educational file, contract).
- Ensure that parents have needed information: Orientation nights with follow-up contact for non-attendees, parent support groups and home visits, home-school contracts, curriculum nights, monthly meetings on topics of mutual interest.
- Create formal and informal opportunities to communicate and build trust: Multicultural potlucks, grade-level bagel breakfasts, family fun nights, committees designed to address home-school issues, principal's hour.
- Underscore all communication with shared responsibility: Share information about the curriculum of the home, discuss co-roles (i.e., co-communicators); adopt a team approach for setting mutual goals for supporting children as learners; implement shared practices (i.e., common language about conditions for children's success).

Enhance learning at home and at school

- Ask parents what they would like from educators: Respond to parents' indicated needs for resources (information, support) (National P. T. A., 1997).
- Provide information: Sponsor workshops or distribute information to assist parents in understanding how students can improve skills, get help when needed, meet class expectations, and perform well on assignments; provide information on how parents can foster learning at home, give appropriate assistance, monitor homework, and give feedback to teachers; provide families with home learning materials (National P. T. A., 1997).
- Structure involvement opportunities: Families and educators share expectations and goals for the student (de Shazer, 1988); encourage the development of a personalized education plan for each student, where parents are full partners (National P. T. A., 1997).
- Recognize what parents are doing at home: Communicate the importance of positive relationships between parents and their children; provide opportunities for staff members and parents to learn and share successful approaches to supporting children's learning at home (National P. T. A., 1997).

Shared decision making

- Individual-level problem-solving and decision making: Encourage and facilitate active parent participation in decisions that affect their children, such as student placement, course selection, and Individualized Education Plans (IEP; National P. T. A., 1997); speak of concerns, goals, and possible solutions, not problems, deficits, or deficiencies; encourage perspective-taking, that is, both parents' and teachers' desires and feelings about a student are important (de Shazer, 1988).
- Involvement in special education planning and decision making: Parents as assessors and presenters of reports, policy makers, and advocates and peer supports (Harry, 1992).
- Involvement in school decision making: Provide understandable, accessible, and well-publicized processes for influencing decisions, raising issues or concerns, appealing decisions, and resolving problems; enable parents to participate as partners when setting school goals, developing or evaluating programs and policies, or responding to performance data; include parents on all decision-making and advisory committees and ensure adequate training for such areas as policy, curriculum, budget, school reform initiatives, safety, and personnel (National P. T. A., 1997).
- Provide training for staff and parents on collaborative partnering and shared decision making.

(Table continues on the following page.)

Table 6. (Continued)

Collaborating with the community

- Invite participation: Encourage employers to adopt policies and practices that support adult participation in children's education; foster student participation in community service; invite community members to be involved in school volunteer programs (National P. T. A., 1997).
- Collaborate with community agencies: Collaborate to provide family support services and adult learning opportunities; distribute information regarding cultural, recreational, academic, health, social, and other resources that serve families within the community; develop partnerships with local businesses and service groups to advance student learning and assist schools and families (National P. T. A., 1997).
- Publicize success: Publicize academic awards, honors, and test results in school and community newspapers; develop a comprehensive awards program that regularly recognizes achievements in all academic areas (Moles & D'Angelo, 1993).

Communication. Communication serves as the foundation for all home-school collaboration activities. Traditionally, communication between home and school has occurred in one direction: from school to home. If we want shared responsibility, then families and schools need to be co-communicators, exchanging information that enables both to assist children's learning (Moles & D'Angelo, 1993). Christenson and Hirsch (1998) recommended six tangible mechanisms for including families and keeping communication channels receptive to family signals:

1. Strive to maintain a positive orientation to all communication between family and school.

2. Develop and publicize regular, reliable, varied two-way communication systems.

3. Keep the focus of communication on child's performance.

4. Ensure that parents have needed information to support children's educational progress.

5. Create formal and informal opportunities to communicate and build trust.

6. Underscore all communication with a shared responsibility between families and schools.

Furthermore, *communications should be in person* whenever possible to avoid barriers for parents who cannot read or who do not speak English (Liontos, 1992).

Enhancing learning at home and school. An objective of National Education Goal 8, home support for learning is a crucial factor in enhancing children's learning. How parents support their children's learning, through words and actions, has positive effects on student achievement (Bempechat, 1998; Christenson et al., 1992). Schools often underutilize this resource. The following steps are ways to stimulate and enhance families' support for children's learning and development:

1. Ask parents what they would like from educators: A good starting point for working inclusively with families is simply to start asking families what it is they would like to see happen for their child, for families at the school, and for the school. It is essential to find out what families desire so that they can be active partners in promoting children's learning. Some roles for school psychologists include conducting surveys or needs assessments about the kinds of information and assistance parents would like to help them facilitate learning at home. Services for families, such as informational meetings on curriculum and school policy, inservices on helping children learn at home, or parent education in specific areas (e.g., parenting, adult literacy) should be based on parents' responses to the surveys and needs assessments.

2. Provide information: Parents often want to help their children with homework or provide learning activities to complement what they are learning in schools. To do so, they report needing information from school personnel about expectations, curricula, and teaching strategies (Scott-Jones, 1995). In their interview with parents about 33 involvement activities, Christenson and colleagues (1997) found that parents wanted more information on how schools function and children's development;

opportunities to interact with school psychologists, particularly about parental questions; and opportunities to dialogue with teachers. Fortunately, techniques are available. School psychologists can create joint interventions with parents, ranging from writing home-school notes, implementing Conjoint Behavior Consultation (Sheridan, Kratochwill, & Bergan, 1996), conducting solution-oriented family-school consultations (Carlson, Hickman, & Horton, 1992), and engaging in structured parent-educator problem solving (PEPS) (Christenson, 1995a).

3. Support what parents are doing at home: Parents do many things to support children as learners, from direct activities to setting expectations. These may include reading books to them, teaching them how to cook, having expectations for their behavior and school performance, and monitoring and supervising their use of time. This information could be used by schools to provide materials and resources to support families' efforts and to identify potential areas for demonstrating to parents other effective ways to help their children learn. The Megaskills Program is particularly noteworthy in this regard (Rich, 1992).

Shared decision making. Shared decision making involves parents and educators working together to improve the school and children's learning through participation on councils, committees, and planning and management teams. Parents and educators are involved in shared decision making at every level: individual child, classroom, school, district, and community (Swap, 1993).

1. Involvement in individual-level problem-solving and decision making: The strong effect of families on children's behavior and learning is rarely disputed. Schools can include parents by creating opportunities for exchange of information by asking parents for their observations/input, sharing expectations and goals for the child, inviting their assistance in addressing the concern, and speaking "our" language (we can do it together) (de Shazer, 1988). Canter and Canter (1991) present a structure to follow when contacting parents at the first sign of a concern that is inclusive, solutions-oriented, and optimistic (Table 7). Sheridan and her colleagues (Sheridan et al., 1996) developed and tested conjoint behavioral consultation (CBC), which is a systematic, indirect form of service delivery wherein parents, teachers, and school psychologists work together to address the academic, social, or behavior needs of a child. CBC consists of four steps: (a) Problem Identification, in which the problem is defined in behavioral terms, a goal is reached for behavior change, and a plan for collecting baseline data is made; (b) Problem Analysis, in which baseline data are analyzed to confirm correct identification of the problem and an intervention plan is developed; (c) Treatment (Plan) Implementation, in which the intervention is implemented and monitored, and training is pro-

Table 7. Canter and Canter's structure for communicating with parents of "potential problem students"

- Plan before you dial. Write down all the points you want to cover with the parent, and keep the notes with you as you speak.
- Begin with a statement of concern. "Mrs. Jones, this is Ms. Williams. I'm going to be Bobby's fifth-grade teacher. I wanted to speak to you because I want to make sure that this year is a successful one for your child."
- Get parental input concerning the problem. Demonstrate your concern for the parent's point of view. "I would like to know your view of Bobby's experience at school."
- Get parental input for what will be needed to make this year more successful. "I'd like to know what you feel we need to do to ensure Bobby has a good year this year."
- Explain that parent support is critical. "I believe you can help me with Bobby. I will be in touch with you throughout the year, because your support is vital. You are the most important person in your child's life, and Bobby must know we are working together to help him."
- Express your confidence. "I have complete confidence that by working together we will help Bobby to have a good year. I want to assure you that I've worked with many children like Bobby before, and I am certain I can make this year a great year for your son."

Source: Canter and Canter (1991).

vided to teachers and families if necessary; and (d) Treatment (Plan) Evaluation, in which teachers and families decide whether the behavior goals have been met and discuss ways either to modify, continue, or terminate the intervention. Effective consultation meetings are based on non-blaming interactions and a problem-solving orientation and structure.

2. Involvement in special education planning and decision making: Most school psychologists spend the bulk of their time involved in special education-related activities. Several openings for meaningful family-school partnerships in educational planning and delivery exist in the special education realm. Federal special education policy mandates family involvement in special education referral and placement; however, it leaves wide room for how families are involved. According to Harry (1992), giving parents a meaningful equal role in special education decision making will require changing the parent-professional discourse. Based on ethnographic research, she developed a four-part classification for establishing equal partnerships between families and schools for making special education decisions. The first role, *parents as assessors*, involves parents in the entire assessment process, drawing on their knowledge of their children's developmental and cultural history that may account for developmental, learning, and behavioral patterns. Second, parents can serve as *presenters of reports*, giving oral or written reports that are official documents and part of the child's educational record. The third role, *parents as policymakers*, involves parents in decision making about special education and cultural or community concerns. Finally, the fourth role involves *parents as advocates and peer supports*. In this role, parents provide peer advocacy, support at IEP meetings, and mutual interpreters between the cultures of the community and of the school. These roles, albeit developed within the context of special education, are equally applicable for general education.

3. Involvement in school problem-solving and decision making: Shared school decision making is incorporated in programs and policy at the local, state, and federal levels. Parents and community members become partners in formal school decision making through varied means—P. T. A./ P. T. O. or advisory councils and committees, assisting in committees to gather information to make recommendations about school policy or participating in decisions about hiring administrators or adopting curricula (Swap, 1993). Direct service actions for school psychologists could include training parent representatives in decision-making skills, collaboration, and ways to communicate with other parents about school improvement activities. However, simply mandating parent participation in activities or programs guarantees neither active participation nor parent influence on child or program outcomes. Some schools have taken full advantage of the opportunities provided by shared decision making (Swap, 1993). An example illustrating the power of a home-school team to focus on educational concerns can be found in the Comer Process (Comer et al., 1996). Structured family-school meetings for individual or systems-level concerns are another relevant example of practice for school psychologists (Weiss & Edwards, 1992).

Collaborating with the community. In collaborating with communities, community resources are used to strengthen schools, families, and student learning (National P. T. A., 1997). Some opportunities for school psychologists to facilitate community collaboration include:

1. Inventory community needs, resources, and values: To develop programs that address the needs and values of the community, educators need to know what exists in the schools and communities regarding needs and existing resources. Two ways to conduct this inventory are resource mapping, which involves depicting what is currently in place in schools and communities and what needs they address (Fetro, 1998), and conducting a needs assessment. The needs assessment could involve surveys or community meetings to solicit information and identify people who are interested in becoming involved in school efforts to support children's learning (Carlyon, Carlyon, & McCarthy, 1998).

2. Invite participation: People and groups seeking to be involved in family-school efforts should feel

welcome. Potential participants to be invited may be identified in the inventory of community resources. It has been recommended that educators consider developing mechanisms to match offers of family or community resources with ongoing programs in the school so they can fill gaps rather than duplicate efforts (Carlyon et al., 1998).

3. Collaborate with community agencies: School psychologists can collaborate with existing community agencies to provide family support services, child and family physical and mental health services, adult learning opportunities, and/or child educational enrichment programs. Such collaboration can further address families' needs and enable them to participate more fully in activities that support education (National P. T. A., 1997).

4. Celebrate and publicize successes: Community collaboration should acknowledge achievements and contributions of individuals and groups to improve the educational programming, opportunity, and success of children (Carlyon et al., 1998).

Creating a family-school team: A prerequisite. A precondition for home-school collaboration actions is to establish a family-school team to address issues that only can be solved with home and school input. The following guidelines are adapted from Fetro's (1998) work.

The family-school team should include key players who have responsibilities for and a stake in promoting student learning, such as teachers, school social workers, school psychologists, administrators, health staff, parents, students, and/or community representatives. The responsibilities of the family-school team could include assessing student, family, and educator needs; mapping existing school and community resources that could contribute to successful home-school collaboration; identifying gaps and duplications in services and resources; developing action plans; and monitoring implementation. Explicit information on action steps to be taken to create family-school teams is provided by Epstein (Epstein, Coates, Salinas, Sanders, & Simon, 1997) and Davies (Davies, Burch, & Johnson, 1992), past co-directors of the federally funded Center on Families, Communities, Schools, and Children's Learning.

School psychologists have several potential roles to play in fostering home-school collaboration, at community, district, school, and individual levels. Table 8 presents a sampling of the types of activities school psychologists can perform under these different levels.

Actions represent opportunities for educators to join with families, enlist, and expand their support to enhance children's learning. However, home-school collaboration is a process, not an event or set of events. These actions serve to reinforce the attitudes held by schools and the relationships between schools and families, and the relationships and attitudes, in turn, influence schools involvement actions (see Figure 1).

Based on research on effective parent-teacher relationships for promoting learning and behavior, Patrikakou and Weissberg (1999) identified seven components of effective family-school partnership programs. Called the Seven P's, these components inform the development of strategies and tools for partnership-building.

1. Partnership as a priority: Each school needs to define for itself the types of partnerships that are most important and then set priorities for interventions that target them. Beyond a mission statement that communicates to families the importance of family-school relationships, this also requires educator training and resources.

2. Planned effort: Effective family-school partnerships are carefully planned and implemented, and parents' needs, views, and patterns of involvement are sought.

3. Proactive and persistent communication: Regular, continuous communication with parents throughout the school year about class rules, expectations, goals, and curricula will involve them in the educational process in meaningful ways (e.g., use their input).

4. Positive: Communication between school and home also should happen when the child is performing successfully. Positive input can be an indication to parents that the teacher sees the whole child, not just his or her areas of weakness.

5. Personalized: What draws parents' attention is specific information about their own child. Con-

Table 8. District, school, and family roles for school psychologists in home-school collaboration

District level

- Write policy and develop performance standards and mission statements
- Evaluate existing home-school collaboration programs
- Promote the benefits of home-school collaboration: getting the word out
- Provide inservices or continuing education to school personnel on partnering with families

School level

- Initiate a needs assessment on what parents and schools would like from one another
- Start a family-school team for promoting and implementing home-school collaboration; participate on the team
- Work with administrators and community/business leaders to fund and start a family resource center in the school building
- Set up a school governance team with family participation
- Follow due process procedures for involving families in special education decision making
- Write a school mission statement that reflects attitudes of partnering and building relationships with families
- Cover a classroom for 1 hour a week to allow teachers time to make family phone calls
- Provide parent education workshops on topics of interest to families
- Establish "family nights" at school
- Write grants for programs and services that support families

Family level

- Work with community resources to coordinate services for families in need
- With teachers, visit homes of families who did not attend parent-teacher conferences or attend IEP meetings to establish relationships with parents, communicate information, share tips on supporting children's development, and learn more about families
- Before assessment or IEP meetings, meet with families to ensure that they understand evaluation results, the content of the IEP, and their rights
- Give parents a role to play at assessment/IEP meetings (e.g., assessor, presenter, advocate)
- Participate and consult in parent-teacher meetings
- Provide parents with the skills to cope with disruptive behavior
- Notice and celebrate parents' contributions to the school through personal notes, articles in newsletters and local newspapers, or celebration lunches

crete, specific examples of their child's strengths and weaknesses can lead to higher levels of collaboration, maximizing the benefits for the child.

6. Practical suggestions: Teachers expand the learning environment beyond the classroom by offering parents practical and specific suggestions on how they can help their child's education at home.

7. Program monitoring: Systematic evaluations of family-school partnership programs can address parent feedback and calibrate partnership practices to increase effectiveness.

The challenge is: Building family-school partnerships takes time. School psychologists often hear about "uninvolved families," or that teachers never see the families they most want to see to address learning issues. Even if schools implement components of effective home-school collaboration programs, we will not see these families unless we have attitudes and relationships that set the context for shared responsibility and positive partnership actions. For example, schools may set up a system of "practical suggestions," but hold the attitude that parents are ineffective at providing rich learning environments at home. The logical implication is that many families will sense this attitude and choose not to be involved. We need to examine our school policies and practices and the messages they send to families, explicitly and implicitly, before saying, "I never see the families I want to see."

SUMMARY

The goal of best practices in home-school collaboration is to support children's learning by building positive connections and relationships with families.

Home-school collaboration focuses on encouraging students to be learners *at home and at school*. Positive family-school partnerships for children's learning are correlated with higher school achievement and positive indicators of school performance.

Important steps for establishing family-school partnerships involve attitudes, relationships, and actions that specifically facilitate home-school collaboration. Attitudes reflecting shared responsibility, recognizing and enlisting parents' expertise, and a solution-based orientation set the context for interactions between families and educators. Relationships with families result from these interactions and provide the impetus for families to feel welcome and motivated to work as partners with educators in addressing student needs. Finally, home-school collaboration actions put shared responsibility and decision making into practice by preventing and solving problems and enhancing children's learning across home and school. Fruchter, Galletta, and White (1992) concluded that effective programs differ in specific activities, but share four tenets: (a) parents are children's first teachers and have a lifelong influence on their values, attitudes, and aspirations; (b) children's educational success requires congruence between what is taught at school and values matched at home; (c) most parents care deeply about their children's education and can provide substantial support if given specific opportunities and knowledge; and (d) schools must take the lead in eliminating or at least reducing traditional barriers to parent involvement. However, schools could utilize these components and still have uninvolved families. When this occurs, educators need to examine their policies and practices—their attitudes toward and relationships with families—that set the context for collaborative actions.

ANNOTATED BIBLIOGRAPHY

Comer, J. P., Haynes, N. M., Joyner, E. T., & Ben-Avie, M. (1996). *Rallying the whole village: The Comer process for reforming education.* New York: Teachers College Press.
This inspiring, practical book describes the highly successful School Development Program (SDP) developed by Comer and initiated in the New Haven, Conn., school district in 1968. Since its initiation, the SDP has been implemented in more than 700 schools and has resulted in improved achievement of its students. The book describes three principles that guide the SDP: consensus, collaboration, and no-fault. The program involves three teams: the Parent Team, School Planning and Management Team, and Student and Staff Support Team, which carry out three operations: Comprehensive School Plan, Staff Development, and Assessment and Modification. The goal of SDP is described as child and adolescent growth along six developmental pathways: physical, psychological, language, ethical, cognitive, and social.

Hoover-Dempsey, K. V., & Sandler, H. M. (1997). Why do parents become involved in their children's education? *Review of Educational Research*, 67(1), 3–42.
Based on psychological theory and research, this insightful review highlights three constructs proposed as central for understanding why parents become involved in their children's education. Issues related to how parents perceive and construct their roles as parents, parental self-efficacy, and involvement messages from the school offer implications for both researchers and practitioners interested in enhancing family involvement.

Liontos, L. B. (1992). *At-risk families and schools: Becoming partners* (ERIC Document Reproduction Service No. EA 023 283). Eugene, OR: ERIC.
This 150-page manual is an excellent, readable synthesis of theory, research, and specific programs about home-

school collaboration for at-risk populations. Topics include communication, home as an educative environment, school readiness, home learning, and decision making. Particular emphasis is placed on early intervention, dropout prevention, and supporting and strengthening families. Elements of successful programs and information on reaching families are detailed.

National P. T. A. (2000). *Building successful partnerships: A guide for developing parent and family involvement programs.* Bloomington, IN: National Educational Service.

The six National Standards for Parent/Family Involvement Programs (Communicating, Parenting, Student Learning, Volunteering, School Decision Making and Advocacy, and Collaborating with the Community) provide the framework for this informative, useful book, of interest to anyone designing and evaluating parent involvement programs. Other resources include strategies for overcoming barriers and developing action teams, and reproducible position statements, surveys, forms, and worksheets helpful for developing family involvement programs.

29 Best Practices in Building Partnerships With Families

Graciela Elizalde-Utnick
Brooklyn College, City University of New York
Bilingual Psychological and Educational Assessment Support Center

OVERVIEW

It is widely accepted that collaboration between schools and families yields positive outcomes in a child's education. It is also widely recognized that parental support is pivotal for successful psychological interventions with children. The 1990s have seen a proliferation of written works filled with suggestions for collaboration and successful partnerships between families and schools. The importance of home-school collaboration is no longer questioned. The focus is currently on designing appropriate and successful partnerships that meet the needs of all parties involved—schools, families, and students.

In order to plan and implement effective and appropriate interventions, school psychologists need to work together with families. As part of their consultative role, school psychologists view parents and other caretakers as partners in the collaborative problem-solving process. In fact, since the late 1960s, G. M. Trachtman (personal communication, 1981) has made the very provocative claim that parents should be considered the primary clients of school psychologists, while children should be viewed as secondary clients. In his work as a school psychologist, Trachtman (1979) viewed the parent as "a valuable member of a team trying to help work out some problem for a child.... The parent was clearly seen as the person most concerned for, most responsible for, and most knowledgeable about the child" (p.384). There is no doubt that the child is always the school psychologist's client; however, the child is not the *only* one.

Accepting the premise that both children and their families are our clients, the school psychologist is in the very important position to strengthen the link between home and school. This chapter highlights best practices in building partnerships between families and schools. It provides (a) a definition of and rationale for home-school partnerships, (b) factors that influence the development of successful partnerships, (c) a framework for family-school partnerships; and (d) strategies for developing successful partnerships.

Partnerships between schools and families are conceptualized as a collaboration, in which there is "the establishment of a mutual goal or shared agenda between educators and parents to improve educational outcomes for students" (Christenson, 1995a, p.254). It includes but goes beyond fostering family involvement in the schools. Christenson, Rounds, and Franklin (1992) distinguish between parental involvement and home-school collaboration, noting that "parental involvement focuses on the parents' role in becoming involved in their children's education, whereas home-school collaboration focuses on the relationship between home and school and how parents and educators work together to promote the social and academic development of children" (p.21).

The empirical basis for developing family-school partnerships is strong. Extensive literature documents the benefits of parent participation on student achievement as well as student affective and social development (Henderson & Berla, 1994; Christenson et al., 1992). In addition to the effect of parental involvement on student outcomes, parent participation impacts on school personnel. Epstein (1996) found that teachers who reach out to parents are more accepting of and are more knowledgeable about families than those who hesitate to be involved with parents. Teachers who involve parents judge them more positively in terms of helpfulness and reliability. They also stereotype families less. In contrast, teachers who do not frequently involve parents rate less-educated parents and single parents as lower in helpfulness and follow through than other parents (Epstein, 1996).

Haynes and Ben-Avie (1996) note that through increased parental involvement, educators increase their knowledge of the sociocultural context of the families and communities they serve. Understanding the daily stressors, linguistic patterns, and how this sociocultural context can impact learning is likely to lead to an increased sense of teacher efficacy and improved classroom climate. Parents are also affected by their participation in school activities (Haynes & Ben-Avie, 1996). Involved parents learn ways to help their children and become motivated to further their own education.

Support for family-school partnerships is reflected in federal policies such as the Goals 2000 legislation. The introduction of the Goals 2000: Educate America Act gives more power to parents to influence the education of their children. It reads, "Every school will promote partnerships that will increase parental involvement and participation in promoting the social, emotional, and academic growth of children" (U.S. Department of Education, 1994, p.11). Other programs such as Title I require consultation and collaboration with parents. Many state and district policies also stipulate that programs must involve all parents and families (U.S. Department of Education, 1997). Furthermore, the 1997 amendments (P.L. 105-17) to IDEA address the participation of parents in the development of their child's program. These amendments require more parental involvement in the decision-making process (U.S. Department of Education, 1997).

Despite federal policy and the strong empirical basis for family-school connections, practices have lagged (U.S. Department of Education, 1997; Vaden-Kiernan & Chandler, 1996). Although progress has been made in some states, schools, and districts, family-school partnerships are not the norm (Christenson, 1995b). Epstein (1992) challenges school psychologists to take an active role in helping schools and families to connect and work together. Likewise, Christenson (1995b) broadly described the school psychologist's role, which is:

> to clarify rights, roles, and responsibilities between educators and parents for children's learning and to ensure that each child has opportunity to learn in his total learning environment—that is, home and school. It is time to share with parents the curriculum of the home. It is time to attend to family resources and to strengthen and support America's smallest school: the family (pp.129–130).

School psychologists must be change-agents in this collaborative process in order to improve life for all children, families, and educators.

BASIC CONSIDERATIONS

The development of partnerships does not happen overnight. It takes effort on the part of all stakeholders. In order to engage in this collaborative process with families, school psychologists must consider family-school partnership principles as well as factors influencing the building of such partnerships.

Family-School Partnership Principles

Family-school collaboration should be an on-going process beginning early in the child's life. It should stress shared goals, mutual efforts, communication, and mutual respect. A good example is the U.S. Department of Education (1997) Family School Partnership. The Family School Partnership confirmed that:

1. There is shared responsibility between the school and the home in order to provide students with a better education and a good start in life.
2. The schools will welcome families and reach out to them before problems manifest themselves.
3. The schools will help families to be included in the decision-making process.

4. The schools will organize tutoring and other such experiences to improve student learning.

5. Families will monitor student attendance, homework completion, and television watching and take the time to listen to and communicate with their children.

6. Families will engage in literacy experiences (e.g., reading to a young child) with their children.

7. Families will become acquainted with teachers and other school personnel.

8. Families will participate in the decision-making process.

9. There will be effective two-way communication between schools and families. This is accomplished by schools minimizing the use of educational jargon and breaking down cultural and language barriers, and by families maintaining contact with the schools.

10. There will be opportunities for families to learn how to help their children succeed in school and for school staff to work with families.

Given these principles, it is important for school psychologists to examine their current practices in order to reach out to all families. The formation of collaborative relationships between families and schools takes time, energy, and commitment. Furthermore, the process is complex in that there are a number of variables that influence the building of partnerships.

Variables Influencing the Formation of Partnerships

Most researchers suggest that parents and teachers can play a critical role in promoting children's education and school success if they work together (Christenson et al., 1992; Epstein, 1996; Henderson & Berla, 1994). Eccles and Harold (1996) point out that even though both teachers and parents think collaboration is important, neither is as involved as the other would like. Based on an extensive review of the literature, Eccles and Harold have identified a number of influences on collaboration between families and educators: (a) family characteristics and beliefs, (b) child characteristics, (c) school personnel characteristics and beliefs, (d) school characteristics, and (e) neighborhood characteristics. Time is also a variable, which affects both families and educators in the process of partnering with each other (Epstein, 1996; U.S. Department of Education, 1998). Figure 1 illustrates the relationship between these variables.

Family Characteristics and Beliefs

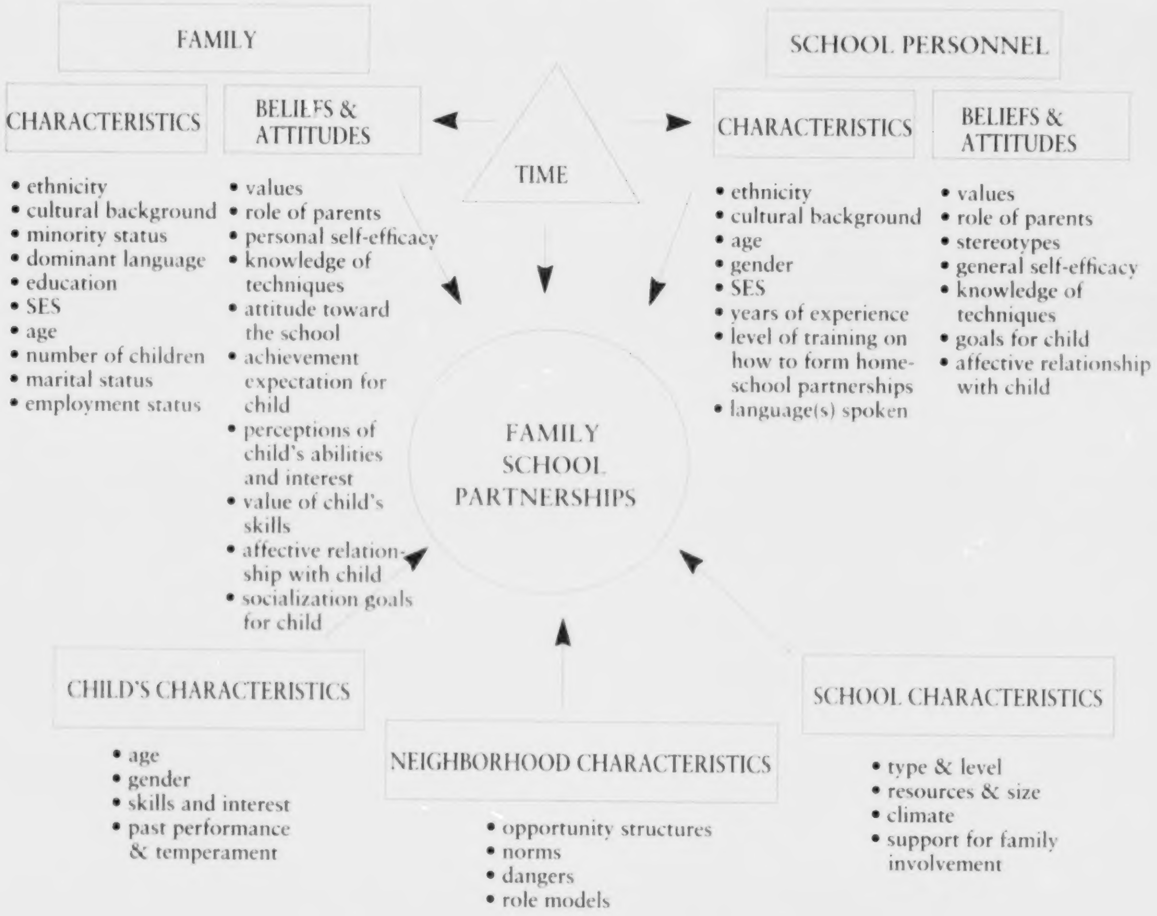
A number of family characteristics influence participation in the collaborative process, including education, financial resources (e.g., socioeconomic status, employment status, number of children), ethnicity and cultural background, minority status, and dominant language. Family beliefs include role of parents, comfort level with school, and knowledge of school policies and available services.

EDUCATION

Level of education is related to parent involvement. For example, better-educated parents are more involved in school and at home (Epstein, 1996). Research sponsored by the U.S. Department of Education (1998) found that less-educated parents had more difficulty helping their children with schoolwork, and this was a significant variable negatively affecting family involvement.

FINANCIAL RESOURCES

Poverty and related stressful life situations can interfere with the collaboration process. The poverty rate for the United States was 12.7% in 1998, with 34.5 million people living in poverty. Of this number, 13.5 million were children from birth to 17 years of age (U.S. Census Bureau, 1999). Poverty exists more often among racial/ethnic minorities. In 1998, the poverty rates for Hispanics and African-Americans were 25.6 and 26.1%, respectively (U.S. Census Bureau, 1999). Child care issues, difficulty with transportation, problems with housing, and dealing with government agencies are some of the factors that can make it difficult for parents to play an active role in education (Kelty, 1997). Employment status is a variable as well, since employed parents are less likely to be involved at school (Dauber & Epstein, 1989). Many working parents find it difficult to fit in



FAMILY
CHARACTERISTICS
BELIEFS & ATTITUDES
• ethnicity
• cultural background
• minority status
• dominant language

appointments during school hours. Furthermore, low socioeconomic status working parents often work long hours and have no control over their own schedules. This leads to limited (if any) time to engage in school activities.

CULTURAL DIFFERENCES

A cultural dissonance between the parents and the school critically affects parental involvement (Comer, 1994). Culture has been defined as a framework that guides behaviors in daily life (Anderson & Fenichel, 1989). It is important to note that even though individuals within a particular culture share similar characteristics and tendencies, they do not necessarily behave in the same way. Families and schools have their own scripts for living and a lack of congruence between these may be a key factor in school failure (Katz, 1991; Ogbu, 1993, 1994).

The Immigrant Experience. The customs and beliefs of culturally and linguistically diverse immigrants often conflict with those of the education system in the United States (Elizalde-Utnick, 1998). Huang and Gibbs (1992) note that school personnel must consider the following with respect to immigrants:

1. Immigrants might have differing cultural expectations of schools based on the educational traditions in their native country that may range from non-involvement to total parental involvement.

2. For some immigrants, cultural expectations of teachers differ, with teachers representing the ultimate authority for educating children; thus, such parents would have learned not to interfere in their child's education. Furthermore, such a parent would not understand his or her role in the collaborative problem-solving process.

3. Some immigrants from war-torn countries, or from rural and/or underdeveloped countries might not have much, if any, experience with schools.

4. Linguistic barriers often exist for immigrant families, and such barriers work against the collaborative process. Even if there is comprehension of the English language, they are often reluctant to speak the language.

5. Immigrants often work long hours and have limited time for school involvement. While one cannot assume that working immigrants do not have time for school involvement, time is nevertheless a critical variable.

6. Undocumented immigrants might be fearful of becoming involved with mainstream institutions due to their immigration status. Such immigrants might fear that information regarding their current status might be given to the Department of Immigration and Naturalization Services.

7. Traditional parental involvement activities, such as PTAs or parenting workshops, might be foreign to immigrant parents. Some parents do not understand that their involvement is both desirable and appropriate.

In addition to these possible variables affecting family involvement, school psychologists should note that close-knit families that prefer to resolve problems within the boundaries of the family would view the professional as an outsider (Kalyanpur & Harry, 1999). While it is important to be sensitive to cultural differences, it is detrimental to generalize and stereotype a particular behavior to all members of a particular culture. Acculturation factors must be considered when attempting to partner with culturally diverse families (Elizalde-Utnick, 1998).

MINORITY STATUS

When trying to establish partnerships with culturally diverse families, school psychologists should be aware of the well-documented literature regarding *minority status*. Ogbu (1994) distinguished between different types of minority status: immigrant, or voluntary minorities, and involuntary minorities. Immigrant or voluntary minorities have moved to a new country for a better life (for economic reasons and/or for freedom), whereas involuntary minorities are defined as people who were originally brought into the United States or any other society more or less permanently against their will (e.g., through slavery, conquest, colonization, or forced labor).

Immigrants as well as involuntary minorities encounter economic and social barriers. Both minority groups encounter interpersonal and intergroup problems in society and school because of cultural and linguistic differences (Ogbu, 1994). Ogbu (1993) found that many involuntary minorities appear to have developed a deep distrust for the public schools, which interferes with their involvement in the schools. Immigrants have been found to be better able to overcome their difficulties. Such ability to cope is attributed to the immigrants possessing a *dual frame of reference* (Ogbu, 1994). Immigrants typically compare current experiences with prior ones back in the country of origin and often conclude that they are better off in the new country. Unlike immigrants, involuntary minorities do not have a "homeland" with which to compare, and, therefore, do not see their situation as temporary. Involuntary minorities tend to interpret the discrimination against them as permanent, institutionalized, and omnipresent (Ogbu, 1994).

While it is important to consider minority status as an intervening variable, stereotyping all individuals based on the voluntary-involuntary dichotomy would undermine the collaborative process. One cannot always say that it would be difficult to involve parents from involuntary minority groups. However, school psychologists should be aware of possible perceptions when interacting with such parents. Likewise, it is not always easy to involve immigrant parents. Immigrant parents, especially if they themselves have little formal education and lack proficiency in the dominant language, are hesitant to intervene in school affairs (Gibson, 1991). Families more familiar with the educational system are more likely to become involved.

LINGUISTIC DIFFERENCES

Language often serves as a barrier between linguistically diverse parents and schools (U.S. Department of Education, 1998). Extensive clinical research documents the need to consider linguistic variables when working with families who speak a language other than English. Bilingual clients who are in counseling often communicate different clinical information depending on the language used during the initial evaluation (Santiago-Rivera, 1995). Marcos (1988) demonstrated that linguistically diverse clients who try to speak English might be more concerned with how to speak correctly than with communicating therapeutically relevant information.

Since language plays such a critical role, school psychologists need to consider how work with interpreters may promote collaboration or the opposite—increase the school psychologist's distance from the family. Even though the use of interpreters should facilitate communication with linguistically diverse families, the presence of an interpreter may interfere with the establishment of rapport (Esquivel & Keitel, 1989). Therefore, it is suggested that when using an interpreter, the school psychologist should be the one that sits closest to the parent. This way, the parent-psychologist partnership develops more naturally rather than that of the interpreter and parent. By not paying attention to these interaction patterns, a lengthy dialogue might occur between the parent and interpreter, inadvertently leaving the school psychologist out of the conversation. Lopez (1995) cautions that the use of interpreters "adds another layer to the complexity of delivering intervention services, complicates issues of confidentiality and trust, and can create barriers in the communication of affect and in the establishment of the working alliance so necessary to the process of working with children and families" (p.1119).

FAMILY'S ATTITUDE TOWARD THE SCHOOL

Families bring different attitudes into the family-school relationship. Families' comfort level with the school is a critical variable in home-school collaboration (Young, 1998). Kelty (1997) found that Hispanic parents rated personal contact with the school prior to an event as the most important element in making them feel comfortable. A parent's sense (or lack thereof) of ownership over the school has also been found to be a decisive factor in parent involvement. Negative views of the school and past negative experiences with education can be barriers to the collaborative process (Chavkin & Gonzalez, 1995; Harry, 1992). Teachers' and other school professionals' communications with families influence parents' feelings of comfort with the school, which then influences parents' involvement in their children's learning (Christenson, 1995b).

Child Characteristics

Families vary their involvement depending on characteristics of the child (Eccles & Harold, 1996). Age is a significant consideration when analyzing child characteristics. Parental involvement is greatest during the earlier years, with dramatic drops as children enter middle school. Eccles and Harold (1996) point out that the trend toward decreased parental involvement as children move into adolescence might reflect the parents' decrease in feelings of efficacy. As children enter the secondary years, schoolwork becomes more advanced, possibly causing parents to feel less confident about their ability to help their children with homework. Eccles and Harold have also found that parents believe they are more influential when their children are younger.

In addition to age, a child's experiences as well as personality variables come into play. Parents become involved more on their own if their children are doing well in school (Epstein, 1996; Eccles & Harold, 1996). The affective relationship between parent and child also affects the degree of involvement in school activities. Parents are more likely to try to help a child with whom they get along than with a child with whom they are having conflicts (Eccles & Harold, 1996).

School Personnel Characteristics and Beliefs

School personnel bring their own characteristics, beliefs, and attitudes into the collaborative process, thereby facilitating or inhibiting it (Eccles & Harold, 1996). For instance, the school psychologist's beliefs, which are embedded in his or her own cultural framework, might be reflected in professional practice. Attitudes about parental involvement can also affect the collaborative process. Like parents, many teachers believe that it is better for adolescents to have less parental involvement (Epstein, 1996). This is particularly the case in minority and low-income neighborhoods where parents are seen as part of the problem instead of a resource (Comer, 1994).

Level of training on how to form family-school partnerships is a critical variable. In an examination of parent involvement activities in public elementary schools during the 1995–1996 school year, the U.S. Department of Education (1998) found that 48% of school personnel indicated that a lack of training in working with parents was a significant barrier.

School Characteristics

School factors are a major influence on parental involvement. Parents are more involved in their children's education when they feel that schools are doing things to involve them (Epstein & Dauber, 1991). School climate and support for family involvement are critical variables (Berger, 2000).

The physical and organizational structure of the school buildings is likely to facilitate or hinder the collaborative process (Eccles & Harold, 1996). For instance, school size typically increases dramatically as children move from elementary to secondary grades. The higher level schools are often departmentalized resulting in less personal contact. Eccles and Harold (1996) note that changes such as these can increase a family's sense of alienation from the school.

Neighborhood Characteristics

A neighborhood's characteristics, such as resources and opportunities, level of cohesion, and role models, can affect family involvement (Eccles & Harold, 1996). Safety in the area after school hours is considered to be a barrier in schools with poverty concentrations and minority enrollments of 50% or more (U.S. Department of Education, 1998). Families living in high-risk neighborhoods with few resources tend to utilize in-home management strategies to assist their children and often focus on protecting their children from the dangers of their neighborhood (Eccles & Harold, 1996).

Time

Time is a barrier affecting both families and school personnel. The U.S. Department of Education (1998) found that lack of time on the part of schools (56%) and on the part of parents (87%) negatively impacts the collaborative process.

BEST PRACTICES

School practices to engage families are strong predictors of family involvement (Epstein, 1996). Epstein developed a well-researched framework of collaboration and family involvement, whereby schools work with families and communities to help them be informed and involved in children's education at school and at home:

1. *Parenting*: Provide parents with the skills and knowledge needed to help their children at each age level. This includes parenting and child-rearing skills, family support, and understanding child and adolescent development.

2. *Communicating*: Communicate with families through notes, telephone calls, conferences, e-mail, and other types of two-way communication.

3. *Volunteering*: Include parents as volunteers and assistants in the classrooms and other areas of school.

4. *Learning at home*: Teach parents to monitor and discuss homework and provide learning activities at home.

5. *Decision making*: Involve parents in decision making, as well as in governance and advocacy.

6. *Collaborating with the community*: Utilize resources in the community to strengthen families, school programs, and student learning and development.

In 1997, the National PTA adopted Epstein's six dimensions of involvement as the National Standards for Parent/Family Involvement Programs to help schools, communities, and parenting groups implement effective parental involvement (Sullivan, 1998). In this same year, the National Association of School Psychologists (NASP) established the National Mental Health and Education Center for Children and Families, which functions as an information and action network to foster best practices in education and mental health for children and families. The Center promotes collaborative efforts and effective strategies by providing resources to parents, teachers, and others working with students and their families.

Strategies for Successful Family-School Partnerships

Best practices involve regarding families as partners in the education of students. Strategies to facilitate this collaborative process include: (a) needs assessment, (b) effective communication, (c) perspective-taking, (d) an accepting school atmosphere, and (e) family involvement activities.

NEEDS ASSESSMENT

One way to improve the relationship between home and school is to conduct a needs assessment or survey to determine what families desire (Berger, 2000). Surveying families early in the school year reveals what families need and suggests ways that the school can foster participation. Families' interests and needs can be ascertained through a brainstorming session, in which all participants contribute ideas for programs. However, some families might be hesitant about making suggestions in a public or group setting. Therefore, anonymous questionnaires can be quite useful. Another vehicle, the suggestion box (Berger, 2000), gives families the opportunity to drop off questions and suggestions throughout the school year. (See Nagle, this volume, for a thorough discussion on needs assessment.)

EFFECTIVE COMMUNICATION

Effective communication is at the core of partnerships between families and schools (Jesse, 1997). Epstein (1996) poignantly makes this case: "From my view, the main goal of partnerships is *to develop and conduct better communications with families across the grades in order to assist students to succeed in school*" (p.213). In fact, frequent and effective communication with families is "as important a part of the school psychologist's job as assessing students and consulting with teachers" (Wise, 1995, p.279).

Two-Way Communication. Effective communication is conceptualized as two-way communication between the home and school (Chavkin & Gonzalez, 1995). In this manner, school psychologists and educators seek information from families as well as provide it to them. Turnbull and Turnbull (2001) go beyond two-way communication, suggesting that communicating among partners can involve three-or-more-way communication, as it occurs in Individualized Education Program (IEP) team meetings.

Communication can take the form of telephone calls, visits to the classroom, or visits to the school psychologist's office. It is important to communicate when good things are happening, not just during crises. While two-or-more-way communication is preferable, schools can provide information through one-way communication vehicles (Berger, 2000):

1. *Newsletters:* Newsletters inform parents about the school's plans and activities. Berger (2000) notes that the use of newsletters is an excellent curriculum tool, since students can write and edit articles.

2. *Notes:* Notes written by school psychologists and educators can update families on student progress and areas of concern. It is important to write notes in a positive manner.

3. *Suggestion box:* When placed in the school hallway, a suggestion box allows families to share thoughts anonymously with school personnel. By posting the comments and replies, this one-way form of communication can be transformed into two-way communication.

4. *Handbooks:* Handbooks can be a rich resource filled with information regarding the school's expectations for students and families. Handbooks can provide information, such as (a) the school's mission statement, (b) discipline policy, (c) procedures (e.g., student progress reports and grades), (d) special school programs (e.g., after-school activities), (e) family involvement practices, and (f) a calendar of school events, including closings, report card periods, parental involvement activities, and open houses (Moles, 1996).

It is important to remember that families have different needs. For example, some parents might only need information (e.g., a newsletter) while others might need information as well as consultation. And, yet, other families might need on-going support (e.g., parenting workshops) (Christenson, 1995b).

In addition to communicating with families, it is important for school psychologists to consult with teachers and other school personnel regarding two-way communication. Through consultation, school psychologists can broaden teachers' views of family involvement; that is, that there are many ways families become involved, both at home and in school. Smith et al. (1997) found that teachers who perceive supportive home and school environments are more likely to engage in strong family involvement activities. School psychologists can help teachers develop more effective methods of communicating with families as well as help teachers develop home learning activities that will foster parent involvement.

Personal Approach. Families often prefer informal communication to formal communication (Turnbull & Turnbull, 2001). However, it is important for school psychologists to consider individual families' preferences in the same way IEPs are individualized for students. By using a more personal approach it not only facilitates communication with many families but also helps diminish the sense of alienation that some parents might be experiencing. Harry (1992) suggests that when attempting to establish partnerships with parents there should be an emphasis on developing individual relationships and providing one-on-one communications, rather than communicating in large-group settings. If large group meetings (e.g., parenting workshops) are the norm, then parents (e.g., those interested in discussing personal examples emanating from the group discussion during the meeting) can be spoken with individually after the meeting.

When providing information relating to the referral, evaluation, and placement of students, face-to-face meetings are better than providing the information solely in writing. Letters should be limited, since the sender is neither seen nor heard. The use of jargon should be avoided, unless absolutely necessary. This author has worked with many illiterate parents for whom letters and other printed material are meaningless. Therefore, oral presentation of information is not only more personal but more comprehensible and effective for those parents with limited education.

Accounting for Linguistic Diversity. Effective communication includes culturally sensitive outreach efforts (Chavkin & Gonzalez, 1995). In order to reduce the language barrier, information, both oral and written, must be provided in the family's preferred language. Ideally, the school psychologist would be the person communicating directly with a linguistically diverse family member (see National Association of School Psychologists (2000) for a directory of bilingual school psychologists, listed by language and state). However, the shortage of bilingual school personnel has lead to the use of interpreters. It is important to keep in mind the potential problems (e.g., maintenance of confidentiality, delivery of accurate information) associated with the use of interpreters (Lopez, 1995). Children should not be used as interpreters, since it places unfair responsibility on the child to communicate and mediate with adults on behalf of his or her parents (Harry, 1992). Furthermore, a child often does not possess high levels of proficiency in both languages, particularly in the use of technical vocabulary. (See Lopez, this volume, for a thorough discussion on the use of interpreters.)

PERSPECTIVE-TAKING: THE RESPONSIVE SCHOOL ENVIRONMENT: A POSTURE OF CULTURAL RECIPROCITY

A responsive school environment is one which enables children to succeed while providing enough continuity that the children do not feel as if they are entering "foreign territory" (Berger, 2000). Berger adds that "the school should be culture-sensitive and respond positively to the language and culture of the home" (p.24). Harry, Kalyanpur, and Day (1999) note that "professionals who are hoping to make a difference for children must be willing to take the initiative in building a bridge between the cultures of diverse families and the culture of schools" (p.7). To do this, school psychologists should initiate a two-way process of information sharing and understanding, a process that can be truly reciprocal and lead to genuine mutual understanding and cooperation. School psychologists, as consultants, already engage in this kind of two-way communication process.

Bianco-Mathis and Veazey (1996) found that the best consultants seem to possess an internal drive to make a difference in the lives of others. But Dougherty (2000) goes farther, noting that, in addition to an internal drive and good consultation skills, effective consultants must have a "personal and professional growth orientation" (p.24). A personal growth orientation involves the consultant's willingness to grow and change as a person. A professional growth orientation refers to the consultant's participation in professional development activities (e.g., professional conferences, staff development workshops) that enhance his or her consultation skills.

One way to grow personally and professionally as well as to establish effective communication is to follow the posture of cultural reciprocity. This involves a multi-step sharing of perspectives between families and school psychologists in order to understand each other. Kalyanpur and Harry (1999) suggest that:

> Professionals [should] adopt this approach whereby they engage in explicit discussions with families regarding differential cultural values and practices, bringing to the interactions an openness of mind, the ability to be reflective in their practice, and the ability to listen to the other perspectives. Furthermore, they must respect the new body of knowledge that emerges from these discussions and make allowances for differences in perspective when responding to the family's need (p.118).

Key Features. The key features of the posture of cultural reciprocity (Kalyanpur & Harry, 1999) are:

1. *Has universal applicability*: The basic construct, communication, involves listening to and respecting multiple perspectives.

2. *Avoids stereotyping*: Avoids the trap of stereotypical solutions by investigating each situation as unique. Families may have differing reasons for the same behavior.

3. *Ensures that both families and professionals are empowered*: The posture of cultural reciprocity enables all parties to engage in a dialogue where each learns from the other.

4. *Goes beyond awareness of differences to self-awareness*: The acknowledgment of difference in perspective is insufficient without nonjudgmental realization of the worldview behind it.

5. *Aims for subtle levels of awareness of differences*: Thus, culturally sensitive strategies that respond to stereotypes, although useful, are insufficient. So, too, are strategies based on more specific knowledge of the families' values but without understanding of the family's point of view. It is critical to understand the assumptions that underlie our practices.

Steps for Developing a Posture of Cultural Reciprocity. Harry et al. (1999) outline the following steps for developing reciprocal relationships with families:

- *Step 1:* Identify the cultural values embedded in your professional practices. For instance, what cultural values are implicit in your interpretation of a student's difficulties or in the recommendation for service? Example: Individuality and independence might be values embedded in your personal and professional identities.

- *Step 2:* Find out whether the family being served recognizes and values these assumptions and, if not, how their view differs from yours. Example: While you might value independence, the family might value interdependence (a value consistent with many non-western cultures (Greenfield, 1994)).

- *Step 3:* Recognize and give explicit respect to any cultural differences identified, and fully explain the cultural basis of your assumptions. For instance, by explaining to a family that your recommendation is rooted in the cultural value of independence, you are offering information about mainstream cultural values. Furthermore, by asking the family for their perspective, you are acknowledging that your cultural beliefs are not the only way to view the world.

- *Step 4:* Through discussion and collaboration, determine the most effective way of adapting your professional interpretation or recommendations to the family's value system.

The posture of cultural reciprocity applies to all families, regardless of whether they are culturally diverse. As Harry et al. (1999) note, "by developing a posture of cultural reciprocity ... you can ensure that every interaction with a family will be a learning experience for both you and the family and that any assistance that you offer will be within the realm of what is valued and feasible for that family" (p.12).

Case Example. Ms. Torres approached the school psychologist because she is having difficulty managing her 15-year-old daughter's behavior. Ms. Torres, a Dominican, single parent, immigrated with her daughter to the United States 10 years ago. For the last 6 months she and her daughter, Claudia, have been arguing frequently about Claudia's friends and the amount of time she is spending with them. Claudia is very angry at her mother's restrictions. She is not allowed to socialize with her school friends after school hours. She is supposed to go straight home after school. During a session with Claudia and her mother, Claudia indicates that she wants her mother to back off and leave her alone. In response her mother declared that Claudia has become "too Americanized," is only interested in herself, and shows very little interest in her family. How should the school psychologist respond? What are the issues involved in the conflict between mother and daughter?

The school psychologist might interpret this situation in terms of the parent-adolescent relationship. From a developmental perspective, we know that early adolescence is a time when conflict with parents escalates. This increase in conflict is often attributed to a variety of factors, including biological changes in puberty; cognitive changes, involving logical reasoning and increased idealism; and changes related to individuation and identity development (Santrock, 1999).

Putting developmental issues aside for the moment, this case can also be analyzed from a cultural value perspective. Applying the posture of cultural reciprocity, the school psychologist should look at each member's cultural point of view, including his or her own. Claudia is demanding greater freedom, which reflects the American value of individualism. Individualism, or independence, is characterized by individual initiative and emotional independence (Triandis, 1995). In contrast, Ms. Torres' demands reflect her cultural value of familism, which places importance on the family over individual needs (Paniagua, 1998). Familism is consistent with collectivism, or interdependence, which is held by about 70% of the world's population (Greenfield, 1994; Triandis, 1995). Collectivism is characterized by a collective identity, emotional dependence, group solidarity, and group decisions. Ms. Torres expects her daughter to put the family over her own individual needs and friends. When she accuses her daughter of being "too Americanized" she is revealing something that many immigrant parents experience with their adolescent children: As their children assimilate to the culture of the United States, perceived changes are often considered threatening to the family's culture. When individuals move to a new country, their cultural values move with them (Greenfield, 1994). Furthermore, immigrants from collectivist cultures (such as Ms. Torres) often hold on tightly to their cultural values because they are trying to preserve their culture.

By looking at each individual's cultural perspective, each value is understood to be adaptive within its social context. But what about the school psychologist's perspective? Why would it make a difference? The school psychologist might firmly believe that Claudia should be individuating and that Ms. Torres should be learning to let go. After all, peers become very important during adolescence, as the adolescent searches for his or her identity. But does this not reflect the cultural value of individualism? School psychologists must be sensitive to different world views and understand them in context. By focusing on cultural differences, the conflict between Claudia and her mother shifts from each one blaming the other to focusing on the acculturation process, which places different demands on the adolescent and mother.

Therefore, in this case, it would be very helpful for the school psychologist to discuss each individual's perspective in terms of culture and the acculturation process. That is, Ms. Torres can come to understand that Claudia is assimilating to the culture of the United States, which places importance on the individual's needs. Furthermore, during adolescence peers become very important. Likewise, Claudia can come to understand her mother's perspective; that is, that her mother is not necessarily trying to exert authoritarian control, but rather out of love and the value of familism Ms. Torres wants to spend time with her and expects Claudia to want the same thing. Once the two understand each other's perspective, they might be able to reach a compromise. The school psychologist can be the link in this collaborative process.

ACCEPTING SCHOOL ATMOSPHERE

A school's climate can enhance or detract from the process of collaboration between families and school psychologists. Berger (2000) describes how schools differ in spirit, either welcoming parents in or, alternatively, maintaining a separatist stance:

> Each school differs in its character (usually set by the administrators) and reflects the morale and attitudes of the personnel. Some say, "Come, enjoy with us this exciting business of education." Others say, "You are infringing on my territory. Schools are the professional's business. Send us your children. We will return them to you each evening, but in the meantime, let's keep to our own responsibilities." In the first instance, there is joy in the educational spirit. In the second, fear and avoidance are dominant. (p.146)

The process of forming partnerships between families and school psychologists necessitates an open-door policy on the part of schools. Furthermore, an open-door policy is more of an attitude than a series of activities (Berger, 2000). For example, the attitude of school personnel is reflected in the welcome or unwelcome greeting in the hall or in the individual's body language.

Schools should also be sensitive to families' schedules and work to provide flexible scheduling of meetings and events that include families. Furthermore, schools that make connections with community resources can help involve families as well as meet other needs within families so as to promote healthy development in children (Smith et al., 1997).

FAMILY INVOLVEMENT ACTIVITIES

The following school activities and resources foster family involvement.

1. Parenting and learning at home
   - Conduct a series of parenting and parent education workshops on a regular basis (e.g., monthly or biweekly). Cover relevant topics related to child development, behavior management, development of literacy, and teaching math and science. *The information should be conveyed in the family's preferred language.*
   - Advertise the workshops through flyers, which have an RSVP section (to be sent in with the child or in an enclosed stamped, self-addressed envelope). Information can be posted on the Internet. Flyers for future workshops should also be disseminated to workshop participants.
   - Increase attendance at workshops by providing the following services to families who need such support (particularly those families who could not otherwise attend):
     a. Transportation assistance (either by providing the actual means of transportation—e.g., school bus—or by providing the round-trip fare)
     b. Child care assistance (either by providing day care for preschoolers, and/or providing an area—within the same room where the workshop is being conducted—with toys for young children to play)
   - Provide refreshments for workshop participants and their young children (e.g., coffee, tea, juice, and donuts). The presence of refreshments fosters a personal, social atmosphere. Participants often remain after the workshop is over in order to converse with each other and the presenter, as well as enjoy the snacks provided.
   - Create handouts and school-home activity packets in the family's preferred language and give them out to all families, not just those who attend the workshops. The handouts can be posted on the Internet.
   - Create a lending library of materials for use at home (e.g., parenting books, magazines, and videos; children's books; educational toys; teaching aides, such as paper-and-pencil literacy enhancing tasks). Again, the materials should be available in the family's preferred language.

2. Communicating
   - Establish personal contact with families.
   - Establish a structure and routine for discussing student progress.
   - Provide printed material (e.g., flyers, pamphlets, and home-school handbooks) regarding meetings and school events. Information can be posted on the Internet. However, follow-up calls are helpful. Information can also be disseminated at events such as back-to-school nights and open houses.
   - Provide information (via print material and personal contact) in the family's preferred language.
   - Establish procedures for two-way communications. For example, a notebook kept in the

child's backpack can be utilized for family-to-educator and educator-to-family communication.
- Implement effective and frequent communication about homework.
- Provide information to parents about course requirements, grading processes, curriculum-related decisions, and other pertinent issues.

3. Volunteering
   - Establish an effective volunteer program, which includes both recruitment efforts and training.
   - Sponsor events and activities that promote family involvement at all levels of development and implementation, such as fairs, carnivals, shared reading, and school projects. Parents are resources that can be used in events such as career day or talent sharing.

4. Decision making
   - Establish a structure and process to include families in decision making.

5. Collaborating with the community
   - Establish a structure for business-school and/or community-school partnership events to enrich school programs and students' experiences.
   - Provide families with information about community resources. For example, create and disseminate a directory of resources in the community. Information can be mailed out to families, sent home with their children, given out at meetings, and/or posted on the Internet.

Case Example. The Family-School Partnership Project (Elizalde-Utnick, 2000) was developed to increase family involvement and home-school communication at Children's Center for Early Learning, a special education preschool and early intervention site in Brooklyn, New York. The school is located in an ethnically diverse, urban community with a student population consisting of 60% Hispanic and 40% African-American or Afro-Caribbean youngsters, ages 0–5, with mild to moderate disabilities or developmental delays. The Project's components include a lending library, parent education workshops, monthly newsletters, individual consultation with parents and other family members, and consultation and collaboration with school staff.

Parenting workshops are offered twice per month, alternating between two themes: behavior management/social-emotional functioning and the development of pre-literacy skills. Parents can also request a topic. Handouts and the monthly newsletter are written in both Spanish and English. The lending library consists of children's books and audiotapes of children's books and songs in both Spanish and English. Families are also given pre-literacy paper-and-pencil tasks (e.g., picture vocabulary cards, vocabulary-building games, sequencing activities) to be used at home. The lending library and pre-literacy materials are made available to teachers and therapists to enhance home-school collaboration. This way, school staff can follow-up with families and discuss the use of these materials in the home and at school.

The Project is evaluated on an on-going basis. Furthermore, a self-study evaluation team was created, consisting of two teachers, the principal, the clinical director, a parent, two New York State Education Department officials, and a local school district CPSE (Committee on Preschool Special Education) administrator. Evidence of project effectiveness includes the remarkable number of workshop participants, including parent cohorts, extremely positive workshop evaluation forms, an increase in the number of materials borrowed from the library; an increase in the number of parents taking their children to the public library, and an increase in the number of parent-staff communications. Furthermore, the parents report generalization of learned skills to the home (e.g., effective limit-setting, establishment of routines, reading to children during the day and at bedtime). The children also provide valuable feedback, as many report parents reading books and playing audiotaped children's songs at home. The teachers and therapists have reported improvement in children's behavior (e.g., increased ability to control impulses, follow directives) and attribute this improvement to on-going collaborations with families. It seems that a partnership has grown between families and the school, which has yielded very positive results for all.

SUMMARY

The purpose of this chapter was to describe the key elements for developing partnerships between families and schools. The importance of family-school collaboration is rooted in the positive outcomes for all stakeholders (e.g., students, families, schools, and communities). Family-school partnership principles and variables influencing the formation of partnerships were described. The current conceptualization of practice regards families as partners in the education of students.

In order to partner with families, school psychologists should (a) adopt a posture of cultural reciprocity, (b) provide families with the skills and knowledge needed to help their children, (c) engage in two-way communication with families, (d) include family members in school activities, (e) guide families so they could help students complete homework and learn at home, (f) include parents in governance and advocacy, and (g) utilize resources in the community to strengthen families, school programs, and student learning and development. Strategies for successful family-school partnerships were described and include effective communication and perspective-taking. With commitment, mutual respect, shared goals, and joint effort, families and schools can work together toward achieving success for all students.

ANNOTATED BIBLIOGRAPHY

Booth, A., & Dunn, J. F. (Eds.). (1996). *Family-school links: How do they affect educational outcomes?* Mahwah, NJ: Erlbaum.

This volume is based on the presentations and discussions from a national symposium on family-school links held at Pennsylvania State University and brings together psychologists, sociologists, educators, and policy makers investigating the bidirectional effects between families and schools. The Epstein (1996) and Eccles and Harold (1996) articles cited in this chapter can be found in this book.

Christenson, S. L., & Conoley, J. C. (Eds.). (1992). *Home-school collaboration: Enhancing children's academic and social competence.* Silver Spring, MD: National Association of School Psychologists.

This is an excellent resource filled with information to facilitate the home-school collaboration process. The content includes theoretical and empirical bases for developing partnerships, a variety of models and programs, and practical approaches for use with different populations.

Kalyanpur, M., & Harry, B. (1999). *Culture in special education: Building reciprocal family-professional relationships.* Baltimore: Brookes.

This thought-provoking book describes the potential impact of embedded and often unrecognized cultural assumptions that influence interactions between families and educators. Personal anecdotes, case examples, and theoretical discussions are included.

Moles, O. C., & D'Angelo, D. (1993). *Building school-family partnerships for learning: Workshops for urban* *educators*. Washington, DC: U.S. Department of Education, Office of Educational Research and Improvement. This resource gives educators strategies for developing family-school partnerships. It contains five staff development workshops to be implemented in elementary and middle schools. Despite the content being focused on urban educators, it is appropriate for use in all schools, including those in rural and suburban areas.

National Association of School Psychologists (2000). *Directory of bilingual school psychologists 2000*. Bethesda, Maryland: Author.
This directory is a valuable resource to school psychologists and school systems. It was compiled by NASP's Multicultural Affairs Committee, in collaboration with the ASPIIRE Partnership Project. The directory lists school psychologists, by state, who are fluent in at least one of 59 different languages.

The National Mental Health and Education Center for Children and Families provides free or low cost resources that address a wide range of issues, including collaboration. The Center also offers information referrals, web links, and access to relevant materials from other organizations in order to facilitate improved communications and collaboration. For materials or further information, the Center can be contacted by e-mail at center@naspweb.org or on the web at www.naspweb.org/center.

30 Best Practices in Facilitating Collaborative Family-Teacher Routine Conferences

Harleen S. Vickers
Kathleen M. Minke
Kellie J. Anderson
University of Delaware

OVERVIEW

In most schools, there are relatively few structured opportunities for parents and teachers to meet during the school year. There are even fewer opportunities for meetings focused specifically on one child. The traditional "routine" parent-teacher conference, scheduled two or three times per year, remains the primary venue through which parents and teachers can develop working relationships that benefit students. However, despite sweeping changes in the larger society (e.g., increasingly complex family structures, greater ethnic and cultural diversity among families), conference methods have barely changed in modern times. Although educators acknowledge that children are more likely to be successful when their interacting environments have mutual regard, supportive communication, and congruent expectations (Bronfenbrenner, 1986), typical conference procedures actually preclude pursuit of these goals.

The prevailing pattern in many schools goes something like this: two or three times a year parents (usually mothers) are asked to come to school to discuss their children's progress. But rarely is there an expectation of an actual discussion. Instead, parents, teachers, and students tend to define the conference as a time for teachers to share their expertise with parents who will listen. Given the importance of the subject matter (student academic progress) and given that the parents and teacher are usually not well acquainted, all parties may approach the task with trepidation. Parents may envision the teacher telling them everything that is wrong with their child and, by extension, them as parents. They may feel defensive and intimidated. Teachers may be equally nervous, wondering if the parents will ask a question they do not know how to answer or if the parent will blame them for the child's lack of success. In this unidirectional process, the teacher talks, the mother listens, and the child stays home hoping the news is not too bad. The mother usually promises to help more at home, and in 15 minutes it is time for the next mother. Rather than developing effective working relationships, these kinds of conferences may result in greater distancing between parents and teachers (Swap, 1993).

Despite admonitions for teachers to create partnerships with parents (National Educational Goals Panel, 1994), this typical conference structure allows virtually no opportunity for parents and teachers to get to know each other or to work together to help the student succeed. Rather, the conference is a highly ritualized encounter that is intended to demonstrate mutual interest in the child and to minimize opportunity for conflict (Swap, 1993). The limited time allotted for conferences serves to keep interactions at a superficial level. Indeed, "in what other circumstance would one allow only 15 minutes to share a significant amount of information about a situation of deep mutual concern with a virtual stranger" (Swap, 1993, p. 20)? However, it is true that time is among the most scarce and precious resources in schools. And although it is important to advocate for increased time for parent conferences, it is equally important to critically examine how we use the time we already have.

School psychologists are in an excellent position to influence change. This chapter offers ways that, as consultants and trainers, they may provide teachers with alternatives to time-honored, yet often unproductive, methods of communicating with parents at conference time. We review two different approaches to parent-teacher conferences: teacher-led conferences and student-led conferences. Both styles emphasize a substantial role for children in the conferences, although the styles differ significantly in roles played by teachers and parents. These conferences encourage children's responsibility for their own learning as a path to increasing their motivation and achievement (Ames, 1992). The desired outcome is to have families and teachers working together in a collaborative partnership to create a context for student success. These alternative methods are currently being used in schools without substantial increases in the time allotted for conferencing.

The chapter is designed to assist school psychologists in creating their own in-service (or pre-service) training activities for teachers. It addresses only routine parent-teacher conferences. Although some of the information presented applies to other kinds of conferences (e.g., IEP and problem-solving meetings), those conferences entail additional skills and issues not discussed here. The reader should note that improving routine conferences is only one small piece of what should be a larger, coordinated set of interventions designed to improve family-school collaboration (see Minke, 2000; Christenson et al., this volume). However, changing the conference style of even a small group of teachers can have far-reaching effects for students, families, and other teachers.

BASIC CONSIDERATIONS

This section describes foundational knowledge that teachers must have to conduct more effective routine conferences. This knowledge is derived from systems theory, solution-focused approaches to problem-solving, and basic counseling skills. Many school psychologists are already familiar with this material; those who are not should complete additional reading or training prior to developing training for teachers. Because these conference styles are not simply "recipes" to follow, teachers must understand conceptual underpinnings of the approach. In this way, when unexpected events occur during conferences, teachers' responses flow easily from their conceptual knowledge. When training teachers to conduct alternative conferences, we directly teach the information in this section.

Thinking Systemically

There is a rich and varied literature available that describes how systems theory can be applied to families and schools (e.g., Bronfenbrenner, 1986; Pianta, 1999). Of the many concepts that could be introduced, two are of primary importance: wholeness and patterned interaction.

Living systems, whether individuals, families, or classrooms, are organized entities that cannot be understood by simply examining contributions of individual members; that is, the whole is indeed greater than the sum of its parts. Consider a teacher who says: "Individually, they are all nice kids, but when you put them together, something happens; they are just a MESS!" This teacher is experiencing the system's concept of wholeness. Each individual and the group as a whole affects, and is affected by, the behavior of every other member. When a member is added, subtracted, or changes behavior in some way, the entire system has to reorganize to accommodate to the change. This concept is important because schooling is an act of bringing children from one system, the family, and asking them to function in a new system or set of systems, classroom and school. This creates a new, larger order system: the family-school mesosystem (Bronfenbrenner, 1986), with an increasingly complex set of rules, expectations, and roles for children that may or may not be the same across settings. By thinking about the whole rather than individual parts, teachers are invited to consider not just how the parent or child contributes to interactions but how their own behavior also plays a role. They are encouraged to look for the source of difficulties not within individuals but within the interactions that occur.

The second, related construct is that of patterned interaction (Minuchin, 1974). Systems develop organized patterns of behavior over time. These patterns are not planned; they evolve. Furthermore, patterns are circular and can result in repetitive cycles in which the same outcomes occur, whether satisfactory or unsatisfactory (i.e., patterns become traditions). Consider the following example of a family-school mesosystem process. Andre, a fifth grader, is acting out in class and yells at his teacher. The teacher loses her temper with him and angrily sends him to time out. Andre tells his mother about his teacher's behavior. Andre's mother expresses her annoyance with the teacher to Andre. He acts out in class. And the cycle continues.

It is important to note that one could begin to describe this problem at any point and that each action is simultaneously a reaction. How you understand the behavioral sequence depends on how you "punctuate" it (i.e., what you choose to describe as the first action). Punctuation is arbitrary; that is, the person describing the interaction *chooses* the starting point. In most cases, individuals choose a starting point that supports their own view of the situation. Andre feels frustrated and, therefore, justified in yelling at his teacher. The teacher is angry at the disruption and feels punishing Andre is appropriate. Andre's mother is angry with the teacher and feels it is okay to let Andre know this. Because participants punctuate the situation in accordance with their own views of reality, they see themselves as "right" and the others who do not share their view as "wrong."

These circular patterns influence future behavior sequences. Consider a somewhat more benign example of how patterns become established. In a routine conference the teacher begins by telling the mother about her daughter's progress. As the teacher talks, the mother learns that she is a receiver of information and in response she sits quietly and asks occasional questions. Both their behaviors affect and are affected by the other's, and these initial behaviors set the stage for future interactions. Recognize also that this pattern may have started in a different way. If the mother seated herself and looked expectantly at the teacher, waiting for him to begin to talk, then the result would be the same: the teacher talking more and the mother simply listening.

These two concepts have important implications for understanding behavior and planning interventions. First, if you recognize that you are entering a circle, then you know that you cannot possibly go back far enough in time to know who "started" the problem. You will seek to understand the pattern rather than try to find a singular "cause." Second, if you are engaged in an effort to understand patterns and individual punctuations that the pattern supports, you will not be placing blame for the problem on an individual. Instead, you will focus on how the pattern can be interrupted and how a more productive pattern can be encouraged. When we turn away from causes and blame, we can move toward understanding and finding solutions.

Becoming Solution-Focused

Solution-focused approaches to counseling (e.g., de Shazer, 1985; Murphy & Duncan, 1997) draw on systems and empowerment theory (Cochran & Dean, 1991), along with brief therapy techniques to afford an immensely practical way to solve school-related problems. From the solution-focused perspective, change is considered inevitable, and contacts between parents, teachers, and students provide the opportunities for change. It is assumed that parents, teachers, and *students* have within them resources to solve problems they face. However, these ideas and competencies become available for use in the classroom only when the concerned individuals are invited to share them. Students, when asked directly about their goals and preferred methods for accomplishing those goals, become effective consultants about their own success.

This process does not have to take a lot of time. Consistent with systems theory, small changes are sought that will produce bigger changes later. Because less time is given to discussing problems, more time is available for generating solutions supporting future success.

When these ideas are applied to routine conferences, it is clear that students and parents must be at least as active in conferences as teachers. Successful routine conferences should result in students taking more responsibility for their school performance. By treating students as knowledgeable consultants on their own learning, focusing on goals and solutions rather than deficits and problems, and by expecting change, conferences can more easily attain this goal.

Communication Skills

If parents and students are to be full, active participants in routine conferences, then teachers must have highly developed communication skills in order to elicit and support this participation. In particular, they must be able to listen actively and respond empathically. Multiple sources are available that describe these skills in detail (e.g., Cormier & Hackney, 1999). A brief summary is provided here.

Listening is the single most critical variable to successful communication. As any good communicator knows, it is not as easy as it sounds. In social situations, a good listener is someone who stays quiet, nods at the appropriate times, and appears interested. *Active listening* is far more challenging and requires intense concentration. Active listeners are engaged in on-going observations of verbal and nonverbal messages being sent, and are alert to multiple levels of meaning and affect being conveyed. They do not become distracted by any single comment, recognizing that they must first understand the other's point of view before attempting to explain their own. They are fully engaged with the struggle to understand, and they use *empathic responses* to further the process.

Empathic responding is the mechanism by which active listeners (a) work to understand what others mean and (b) communicate that understanding back to the speaker. These responses reflect the deep meanings and feelings that are being communicated and convince others that they are being heard. Empathic responding leaves no room for opinions, advice, or judgments about what was said. Instead, when teachers send consistent messages that they hear and understand the parents' concerns, parents are encouraged to tell their stories. When parents feel valued, heard, and understood, they are more apt to view the teacher in a positive light and, in return, to listen to information the teacher wishes to share.

Teachers convey their acceptance of and respect for other participants through active listening and empathic responding. All other aspects of the conference depend on the quality of these communication skills (Studer, 1993/1994), but, unfortunately, parents report that we often fail them in this area (Turnbull & Turnbull, 1985). This is not surprising because few educators are taught these skills. Simply telling teachers that they should "listen" to parents is rather like telling students that they need to "behave." It is a laudable goal, but lacks specificity. Without explicit instruction, practice, and feedback on performance, improved communication skills are difficult to master. Therefore, we turn our attention to ways in which these skills can be developed and applied to routine conferences.

BEST PRACTICES

> "I've been amazed at how often the children, the parent, and I had the same concern. The children especially. I guess we've never given them enough credit to know exactly where they're having trouble....Their ideas [for improvement] are amazing....They were demanding of me to keep track...of what they are working on....The ownership of it was amazing."
>
> —Teacher discussing family-school conferences

> "The parents...loved this kind of conferencing. They saw such value....They came back excited....I had one parent come back with something from the Internet [about] ways to help your child at home...and she asked me what I thought of it. I thought, oh my gosh, I never had parents come in with things like this...."
>
> —Teacher discussing family-school conferences

> "I never come to parent-teacher conferences, but I'll never miss another one of these"
>
> —Parent discussing student-led conferences
> (from Seliner, 1997)

> "I think [doing student-led conferences] really does make a difference. It's definitely easier because you know the outcome of the conference and you don't get the jitters and all worried wondering about the outcome. . . ."
>
> —Sixth-grade student (from Austin, 1994)

These quotes come from teachers, parents, and students who have experienced the success of the alternative conference styles described below. In *teacher-led conferences*, which we call family-school conferences, teachers use their knowledge of systems theory and communication skills to engage students and parents in the conference process. Teachers use specific preparation methods and follow a flexible, yet structured, format to elicit student strengths. In *student-led conferences*, teachers have a less active role in the actual conference. Rather, they help students evaluate their own work and prepare them for presenting this work to their parents. This style allows many conferences to take place at once in the classroom, with the teacher acting as host. School psychologists providing training should invite teachers to consider both styles and determine collaboratively which approach is most applicable to the particular school and community.

Family-School Conferences

Family-school conferences are designed to be collaborative conversations among all individuals concerned with the student's success, including the student, teacher, primary caregiver(s), and as many other adults as possible who have a significant role in the student's life. The term "collaborative" denotes that everyone is working together in specific ways; "conversation" makes explicit that this is not a one-way telling of information by the teacher. Collaborative conversations "improve relationships, foster understanding, increase competence and lead to more lasting change.... Collaborative practices emphasize the importance of partners teaching each other about personal experiences, goals, and possible solutions. The aim is not to convince others of solutions and competence but to ask questions and understand experiences in ways that illuminate resources and spur people to action" (Koch & McDonough, 1999, p. 11).

There are four major outcome goals for this type of conference. First, each participant will be both a teacher and a learner; everyone will have the opportunity to share important points and listen to those of others. Second, expectations about and plans for the student's success will be developed collaboratively. Third, students will leave feeling greater ownership of their own learning. Fourth, all participants will leave feeling optimistic about each person's contribution to the student's future success.

TRAINING SEQUENCE

To conduct family-school conferences, teachers need specific instruction, practice, and feedback. School psychologists developing this training should plan to provide a minimum of 6–9 hours of initial instruction/practice followed by a minimum of 6 hours of "refresher" sessions and feedback on videotapes of actual conferences.

The training sequence involves three major tasks. The first task is to help teachers *think differently* about families, schools, and problems. Teachers are provided information on systems principles and collaborative approaches. Once they see that there is a different way to conceptualize the relationships between families and schools, they can begin to understand different intervention alternatives. As part of the second task, teachers learn how to *talk* to families in ways that encourage dialogue and collaboration through communication skills training and an introduction to solution-focused strategies. The third task introduces specific methods to *conduct* and evaluate routine conferences. Each of these tasks is discussed in more detail below.

Task One: Understanding Systems Principles and Collaborative Approaches: The CORE Model. We have summarized important information about systems theory and collaboration under the acronym CORE. That is, following any encounter between families and schools, the goal is to have all participants leave feeling more Connected, Optimistic, Respected, and Empowered than they did prior to the encounter. These four CORE elements maximize the opportunity to collaborate effectively with families. In the model, collaboration is seen as far more complex than simply working together on a problem or issue; it involves a complete reorganization of the ways in which parents and teachers work together.

We teach the CORE model to teachers in a fairly didactic way. Ideally, the group will read about the model in advance (Minke, 2000; Minke & Vickers, 1999; Vickers & Minke, 1997) to reduce presentation time. Regardless of how this information is shared, we encourage a lively discussion and debate as a means of modeling the communication strategies taught later in the training. We focus on how the model is applied to routine conferences by describing the beliefs (italicized below) associated with each model element.

Connecting. The degree of connectedness within a system is a widely accepted measure of system functioning (Olson et al., 1983). Such connections foster trust, and *trusting relationships are the backbone of* *collaborative efforts.* In conferences with families, teachers foster connections by using clear and open communication and encouraging mutual sharing of beliefs and goals. Disagreements are expected and valued; what matters is that everyone's view is heard and given serious consideration. Further, when teachers approach families in ways consistent with the other three CORE elements, positive connections will develop.

Optimism. A hopeful attitude springs from the system's premise that behavior occurs in predictable, circular patterns. *No one person can be seen as the cause of a poorly functioning system.* Instead it is assumed that all individuals involved are *doing the best they can;* the challenge is to develop a full understanding of others' positions. To become more optimistic, teachers are encouraged to recognize how the system contributes to both failures and successes and how each member can influence the outcomes. Each system member is presumed to be capable of doing what is necessary to learn and to change. This is an especially helpful premise in working with diverse families. Because "different" is not synonymous with deficient, teachers learn to concentrate on family strengths rather than weaknesses. By approaching families with optimism, educators consistently send the message: "We can work together."

Respect. To connect effectively with families, educators must treat all families with respect. Respect assumes that each family member is concerned and caring and has the *right to differing values.* Respect also assumes that each participant has valid expertise to offer; each person is both an *expert and a learner* during the conference. Families know their children best, but they are also eager to hear how others see their child. Sometimes families may have little confidence in their own expertise or feel intimidated by professionals and need some encouragement to share their knowledge. By entering conferences with the expectation of being learners as well as teachers, and by using communication strategies that allow families to share what they know, educators can model respect and concern for families' views.

Students warrant the same respect that adults accord each other. Because they are central parts of the mesosystem, *children must be active participants.* When children participate, they have the opportunity to witness adults working together on their behalf and to personally hear adults' expectations. They can also share their expectations of the adults. Because everyone is present, there is less opportunity for misunderstandings. Further, students can be active contributors to any plans for change that are made. Like parents and teachers, students are more likely to be committed to plans they had part in developing. Educators may have reservations about including students and trainers must be prepared to fully process their concerns (see Minke & Vickers, 1999).

Empowerment. Empowerment refers to providing individuals with the opportunity to demonstrate their skills and competencies, usually in arenas where opportunities to do so have traditionally been limited. Within the education context, the general goal is to increase the self-confidence and assertiveness of parents and guardians in promoting their children's education (Coleman & Wallinga, 1999–2000). However, because *power and responsibility are shared,* it is essential that all members of the partnership, including students and educators, feel capable of making decisions and taking individual action. Identifying each person's particular skills and strengths de-emphasizes deficits and concentrates on what can be done differently.

When families and educators experience a sense of empowerment, it relieves any one participant (usually the teacher) from the burden of being an "expert" on everything. Rather than "teaching and telling," teachers focus on listening and understanding. Each individual is supported in expressing his or her own views and participating in the development and enactment of plans for continued success.

An effective method of dis-empowering others is to give advice. Therefore, *advice is avoided.* Advice, even when solicited, relieves the other of responsibility for the solution. Also, once used, it tends to become a major mode of communication. Even worse is unsolicited advice, which is often construed by the receiver as implicit criticism of his or her skills and abilities. When there are issues to resolve, teachers are encouraged to use effective communication skills to help the family generate and evaluate its own ideas rather than immediately offering a single "best" solution.

Task Two: Effective Communication Skills. Thinking differently about families as with the attitudes, beliefs, and expectations described above is essential to successful collaboration with families but, by itself, is not sufficient. Thus, the model also requires teaching the skills needed to listen actively and respond empathically to families. We focus on a relatively small number of skills, including attention to nonverbal cues, reflective and empathic responding, modeling the collaborative role, searching for strengths, and reframing. We stress how to use these skills when delivering and receiving both positive and negative information and blocking blame (see Minke, 2000).

Multiple written and role-played exercises are used to assist teachers in becoming comfortable with the skills. For example, while coaching teachers to search for strengths, we remind them that families often tell stories of defeat and desperation. It is natural to feel sorry for them and to convey that sympathy. By using the following example we illustrate how it is more helpful to highlight the family's strengths when responding. A single father says, "I don't usually get much sleep because I work the night shift. I stay up to get my daughter off to school and then do housework until she comes home at noon. Then I take her to my mother's house and sleep until the other kids get home from school." We present a typical, sympathetic response ("That must be really hard on you.") and then ask teachers to provide an alternative, empathic response that emphasizes the family's strengths (e.g., "It sounds like you really care a lot about your children to make such sacrifices for them. They are fortunate to have such a devoted dad."). Similar scenario exercises are offered for each skill taught. Table 1 shows an exercise that requires use of multiple skills. In some cases, only the dialogue column is presented. Teachers generate both alternative responses and a rationale for them. For groups having more difficulty with the skills, both the dialogue and rationale columns are presented to assist teachers in developing alternative responses.

Teachers should also practice avoiding jargon. Using a vocabulary unfamiliar to parents is confusing, sets up a unidirectional process, and creates a non-collaborative experience for all parties (Rotter, Robinson, & Fey, 1987). During training, teachers can make a list of frequently used educational terms and write alternate, more easily understood words to substitute (Fredericks & Rasinski, 1990).

Task Three: Preparing for and Conducting the Routine Conference. Training proceeds more easily with a step-by-step guide to the conference format. Development of this guide should be a collaborative effort between trainers and teachers, so that circumstances unique to the group can be considered. However, each of the following areas should be discussed.

Consider carefully who should participate. Minimally, participants include one or more teachers, one or more parents (or guardians), and the student. For older students who have more than one teacher, it is best to have a single conference with as many teachers as possible. This may require some creative scheduling among teachers and families. If the child has two parents, then every effort should be made to get both points of view. If parents are divorced, then the parents should decide whether separate conferences are desirable. In addition, if there are other significant caregivers, such as day care workers or grandparents, then parents should be encouraged to invite them.

Prepare participants. Preparations by all participants are essential to a smooth and productive conference (see Table 2). Developing preparation documents and activities for parents and students as part of training is valuable, not only in fostering feelings of competence, but also in eliciting potential difficulties that must be addressed (e.g., providing child care for young siblings).

Asking parents and students to prepare is a demonstration of optimism, respect, and empowerment. It underscores the critical roles they play in the conference. Table 3 shows a sample letter of invitation to parents. Teachers should prepare students for their roles by helping them develop their own lists of strengths and areas for improvement. Students should practice introducing their parents and teachers to each other.

Encourage teachers to carefully consider information they wish to share in the meeting. A mental survey of the child's specific academic, social, and emotional progress may be helpful. Teachers' preparation is considered an ongoing process in which the teacher remains alert throughout the term to stories, products, or events that the parent would like to know about (Bjorklund & Burger, 1987). These observations form the basis for anecdotes that convey the teacher's

Table 1. Communication skills practice

Dialogue	*Alternate Response*	*Rationale*
Parent: I know David is a slow learner, but I just hoped he would be reading better by now. **Teacher:** Don't worry. He really is doing as well as can be expected given his abilities.	You sound worried about David. Tell me some more about what you are seeing with his reading.	Empathic response • clarifies: seeks to understand parent's concerns more fully • validates parent's view • avoids opinion • avoids minimizing
Parent: I don't really understand all of the information in her testing reports. Are you saying Serita can't learn? **Teacher:** To be honest, I think Serita's difficulties have more to do with her attitude and behavior than with a learning disability.	No, I believe Serita can learn. Tell me some more about your questions so we can figure out how to get them answered.	• answers question directly • seeks information • avoids the expert role • avoids opinion
Parent: What do you see as Jeffrey's main problems? **Teacher:** Well, he is pretty unmotivated, he can be lazy sometimes, and he can be quite disruptive during math class.	Sometimes I find it hard to get Jeffrey interested in class projects. What have you found at home that really sparks his interest?	• is clear and specific • asks for parent's opinion • avoids labeling • avoids laundry list of problems
Parent: What do you see as Mark's main problems? **Teacher:** Oh, I am so sorry to have to tell you this but he may be socially and emotionally disturbed. That is why we want to do the testing.	There are a few things we are working on with Mark: helping him behave appropriately with the other children is one. How does he do with his brother and sister?	• provides specific behavior of concern • asks for more information • avoids sympathy • avoids jargon • avoids labeling • avoids expert role
Parent: Kelly is so impulsive! Will she always be like this? **Teacher:** Oh, I'm sure she will grow out of it. Lots of kids go through these stages.	Kelly can be very energetic and spontaneous. In what kinds of situations do you find those qualities upsetting?	Reframing response • effort to set up situation where parent can appreciate the positive side • avoids cliché • avoids opinion • avoids discounting

understanding of the child "as a total human being" (Manning, 1985, p. 344).

Preparation of the environment is particularly troublesome in many schools. However, it is important to provide adult-size chairs and to avoid sitting behind a desk (Wolf & Stephens, 1989). In addition, it is essential to assure privacy and confidentiality during the conference.

Develop a Flexible Conference Format. Each conference should have a logical beginning, middle, and end (see Table 4). To emphasize from the first that students have a central and active role in the conference, they are asked to introduce the adults to one another. Some small talk may follow; the teacher makes eye contact and tries to connect with each participant. The teacher then provides some "structuring" of the process, reminding participants of goals of the conference and how discussion will proceed.

The student is given the opportunity to speak first. The teacher attempts to elicit others' perspectives on each of the student's points, allowing a conversation to develop. This conversation constitutes the "middle" of the conference. If the student offers that he or she feels especially successful and interested in reading, then the teacher opens the topic to others by saying, "What have you noticed about reading?" If the teacher had included reading among the points that

Table 2. Preparing for a family-school conference

Prepare Parents:

- Develop a letter describing the meeting. Include time, place, options for rescheduling, and the amount of time the meeting is expected to take.
- Ask parent(s) to invite any other significant adults in the child's life (e.g., daycare provider, grandparent). Be clear that this is an option not a requirement.
- Ask parent(s) to bring the student with them to the meeting. You may want to include a rationale for including the student that conveys the positive and proactive tone you hope to have in the meeting.
- Ask the parent(s) to write down their thoughts about what is going well and not so well for the student plus one or two key issues they wish to discuss in the meeting. Encourage them to talk with the student. You may wish to include a separate piece of paper with a limited number of questions for them to answer.

Prepare Yourself:

- Make your own list of what is going well and not so well for the student. Try to limit yourself to the most important pieces of information you need to convey. Avoid creating a laundry list of problems. If desired, prepare a folder of work samples or test results that illustrate key points.
- Think about anecdotal stories that underscore the child's uniqueness and will convey to the parents that you have a connection with their child.

Prepare Students:

- Take some time in class to prepare the students for their participation. Emphasize that they will have an active role in the conference.
- Explain the conference procedure (e.g., "This will help us all work together to help you do well in school.").
- Help the students practice introducing you to their parents.
- Ask individual students to share with you (or to write down, if old enough) their thoughts about what is going well and not so well this school year plus anything they wish to discuss in the meeting.

Prepare the Environment:

- Try to find a comfortable space with sufficient adult-sized chairs.
- Eliminate physical barriers. That is, do not sit behind a desk. Arrange chairs in a circle, if possible.
- Consider offering refreshments.

he or she wanted to mention, then it is appropriate to do so briefly after others have addressed this point. The teacher may offer specific work samples or test results to illustrate the comments. When the discussion seems complete, the student is encouraged to state another point he or she wishes to make. After the student exhausts his or her list, and each point has been discussed, the teacher asks the parents if they have additional points. Each of these is explored in turn, making sure the student has an opportunity to comment throughout the discussion. Ideally, following this iterative process of pursuing information from the student and parent, the teacher will not need a turn because the important issues would have been collaboratively discussed already, with the teacher providing input at appropriate times. However, if all of the teachers' points have not been covered, then the teacher brings them up at this time, again encouraging others to comment.

Facilitating this kind of conversation is a difficult skill to master. Teachers are called on to use effective communication strategies to ensure that everyone feels heard and valued in the conversation. They need to check back with participants several times to be sure that each individual has had his or her say. Sometimes strengths and concerns blend together and the teacher must be sure that the student and parents have had the opportunity to discuss all of their issues. For example, assume that during the part of the conference when concerns are being discussed, a father mentions his daughter's interest in science and how she loves the classroom butterfly farm, but he also notes that she has trouble spelling when she tries to write about butterflies. The teacher would invite others' views (including the child's) on spelling, then contribute her thoughts about the students' spelling skills. The teacher would also be careful to validate the positive part of the parent's message; that is, the

Table 3. Sample preparation letter for parents

To the family of ________________________

This year I will be using a Family Conference model for conferences. I believe that a more productive conference involves the teacher, the student, and the student's family. During the conference we will discuss your child's progress so far this year, and I will have samples of your child's work to share with you.

Please bring your child with you to the conference. Also, please think about the following questions, and jot down your thoughts before the conference.

- What are two or three things I am most pleased about in my child's school performance this year?
- What do I think my child needs to improve on?
- What are my hopes for my child during this school year?
- What are other issues or concerns I would like to talk about?

Please bring your notes with you to the conference. I will be working with the children in the classroom to help them think about these same questions. You may want to discuss the conference with your child as well. You may also wish to invite other adults important in your child's life (e.g., grandparents, other caregivers).

As we discuss your child's progress we will develop together any plans that we believe are needed to continue to support your child's success at school.

Please let me know if the following time is convenient for you to meet:

Date: Time: Place:

If not, please write or call with suggestions of other, more convenient times. I am looking forward to meeting with you and your child.

student's enthusiasm for the science project. Finally, the teacher would return to the father to determine whether there are other points he wishes to discuss.

Some time in each conference is spent on developing a plan to support the student's continued success and to tackle needed improvements. This plan should be specific and clearly doable. Insofar as possible, the plan should be elicited from the student. Each participant should have a role in the plan; that is, a specific action each will take to ensure success.

The final part of the meeting includes summary and follow-up. The teacher can summarize or invite one of the participants to give his or her view of what has occurred. No matter who does it, each person should have the opportunity to add or subtract until there is mutual agreement. The last agenda item is to determine if follow-up is needed. Follow-up should be very specific. That is, there should be explicit discussion of how participants will know that the plans they developed are working and when this evaluation will be made.

The issues addressed in a routine family-school conference should be relatively minor ones, such as homework completion, talking out of turn, or mild misbehavior. The main thrust of the conference should center on what is going well and how this success can continue to be supported. Significant problems such as retention and IEP development cannot and should not be addressed in the 15–20 minutes that are usually allotted for routine conferences. Collaborative problem-solving meetings (see Vickers & Minke, 1997; Allen, this volume) provide a format for resolving more serious issues. If such issues arise unexpectedly in a routine conference, then part of the follow-up plan should be to conduct a problem-solving meeting.

Evaluation of Conference Effectiveness. A final step in training is to develop a form for teachers to evaluate their effectiveness in conducting conferences. The sample (Table 5) serves both as a reminder of the skills teachers are trying to use and a method of iden-

Table 4. Conference format

Introductions:

- Ask the student to introduce everyone.
- Begin connecting with all participants by using the communication strategies we have discussed (e.g., make eye contact, thank them for coming).

Structure the process:

- Give a short description of the agenda (i.e., everyone will have a chance to share, conference will take around 20 minutes, at the end plans for continued success will be made).
- Ask student to begin (e.g., "We are here to talk about your progress in school so far this year. I believe you had some ideas you wanted to share, so let's do that first.").

Create a conversation among the participants:

- Encourage participants to comment on each of the student's contributions by asking if others have noticed the same strengths/needs.
- Once the student's list is exhausted, give parents an opportunity to discuss additional points that were not mentioned by the student.
- Integrate your own observations and comments at appropriate points in the conversation. The goal is to cover your own points at natural times in the conversation. If you have additional points, then add them after all the other participants have given their input.

Develop plans to support ongoing success:

- Elicit agreement about one or two areas that need work.
- Ask the student for ideas on how to address these areas. Give each individual at the meeting an opportunity to give ideas and to have a role in the plan.
- Recognize if there are serious problems to be addressed. If so, then schedule a separate problem-solving meeting.

Summarize and plan for follow-up:

- Either summarize the meeting yourself or invite one of the participants to summarize. Be sure to agree on a specific time and method for following up on the plan's success.

tifying areas where additional practice might be needed. It is also helpful to build a set of frequently asked questions with answers for teachers to take with them to solidify aspects of training (see Table 6).

Practice and Feedback. Changing from traditional to more collaborative conferences is quite challenging. Teachers value the opportunity to practice in controlled (role play) settings first, followed by feedback on "real" conferences. In setting up role plays, it is helpful to move from easier situations (i.e., examples in which the child is doing well) to more difficult situations (i.e., examples in which the parent and teacher have a strained relationship). Table 7 shows a sample we use for a child doing well academically with some mild social concerns. Teachers themselves generate many of the more difficult scenarios; this process allows them to try out their skills in a safe environment with a situation they find anxiety provoking.

Following the initial training sessions, teachers videotape one or more of their actual family-school conferences. Teachers may be reluctant to do this at first. However, once they try it, teachers report feedback from videotapes as among the most valuable parts of training. Tapes may be reviewed either individually or in groups. Both methods have merits. Individual feedback allows assistance without embarrassment in front of peers. However, group feedback is less time-intensive and offers the benefit of teachers learning from each other. It is probably best to let the trainee group decide the feedback method, if time permits. In either case, trainers need good supervision skills to provide feedback in helpful ways. We show strengths of the tapes as "highlights" and use the positive reframe of "missed opportunities" to review parts of conferences that were less consistent with the skills taught.

OUTCOME DATA ON FAMILY-SCHOOL CONFERENCES

We are engaged in ongoing research evaluating the effectiveness of the family-school conference method. The comments below are from a group of five ele-

Table 5. Conference Evaluation Checklist for Teachers

Prepared parents:

_____ Letter sent asking for meeting.
_____ Form included to help parents organize thoughts.

Prepared yourself:

_____ Reviewed child's work and developed list of a few key points to be communicated.
_____ Developed comments designed to highlight child's uniqueness.

Prepared students:

_____ Explained procedures.
_____ Practiced having students introduce the adults.
_____ Helped students develop list of strengths, needs, and comments.

Prepared environment:

_____ Comfortable adult chairs
_____ Avoided using desk as a barrier.

During the conference, to what extent did I accomplish the following (use scale of 1–5 with 1 meaning not at all and 5 meaning a lot):

_____ Introductions; connected with each participant.
_____ Invited child to share first and provided ample time for child to present comments.
_____ Invited parent to share and provided ample time for them to express comments.
_____ Integrated teacher comments as appropriate and introduced additional points, as needed.
_____ Used effective communication strategies (attended to non-verbals, reflected, highlighted strengths; used clear, jargon-free language; focused on specific behaviors).
_____ Responded effectively to negative information (validated concerns, asked for clarifications, summarized, and checked accuracy of understanding before problem solving).
_____ Developed plans collaboratively as needed to support success or solve problems.
_____ Elicited or provided a summary of the conference.
_____ Determined what, if any, follow-up is needed.

To what extent did the following occur in your judgment:

_____ Each participant left the conference feeling hopeful.
_____ Each participant left the conference feeling a part of the solution to any problem.
_____ Each participant left the conference feeling heard and understood.
_____ The parents left the conference feeling in charge of their child.
_____ I (the teacher) left the conference feeling in charge of teaching the child.
_____ The child left the conference feeling in charge of his or her own learning.

mentary (K–4) teachers who participated in a sequence of training and practice; they have conducted family-school conferences across two school years. These teachers noted a number of positive outcomes. Parents reportedly came to the conferences more often, brought more extended family members with them, were more prepared for and active in the conferences, and participated more fully in their child's education after the conferences. Students reportedly were more excited about their own learning and progress following the conferences; several teachers noted their surprise at the quality of the students' input on how they learn best. Teachers also felt they learned a great deal more in the conferences than they did in traditional conferences. They observed family dynamics and developed a greater understanding of the child's preferences, strengths, and needs. One teacher noted that the process eliminated trial and error in problem solving. When she offered children a choice from a menu of her ideas, she found that she often had to go through several steps before the problem improved. In the new format, because ideas

Table 6. Frequently asked questions and possible responses

Will I have time to do this?

- Teachers using this format have found that it can be done in the same amount of time as traditional conferences.
- Once you have sample videotapes you can share one with the faculty and note its length.

What if the parent becomes angry?

- Use reflective listening and empathic responding to understand the parent's views without becoming defensive.
- If this is ineffective in reducing the parent's anger, then consider calmly ending the meeting by planning a problem-solving conference for a specific future date.

What if I can't think of anything to say?

- Try summarizing what you have already heard. This will usually get you back on track.

What if I say the wrong thing?

- It is fine to state directly that you are concerned that what you've just said is not what you really wanted to say. Take a minute to think about what you wish to convey and try again.

What about giving test scores? What if I have to discuss retention?

- If students are to benefit from the administration of tests, then they need to know where they are relative to district and national standards. Avoid an emphasis on ability. Rather, emphasize that with hard work and practice even low scores can be improved dramatically. Focus the discussion on how best to improve the situation.
- If ongoing, two-way communication is in place between the family and the school, a discussion of retention should not be a surprise. Because the student is the one who must cope with the retention, it is best to have the student understand as clearly as possible the reasons for it.
- Except for the very youngest, students who are doing poorly already know it. Discussing their difficulties outside their presence does not "protect" them. Rather, it denies them the opportunity to participate in solving their problems.
- In rare cases, consider having a discussion with the parents outside of the student's presence until the adults have become comfortable with the available options. Then bring the student into the discussion.

What about the parents who just won't come?

- Be sure you are offering as many options as possible for parent participation (e.g., holding conferences in the evenings and/or in community rather than school settings). Offer childcare for siblings.
- Rely on word of mouth. Over time, as parents become more comfortable with conferencing, the word may spread throughout the community.

I teach young children. Can they really do this?

- Children as young as preschool can be actively involved in at least some phases of the conference (Bjorkland & Burger, 1987).
- Younger children may require more time and support in preparation and participation (e.g., more direct questioning, teacher recording of responses for use in meeting).

came from the child directly, the first plan typically worked. Finally, several teachers noted that they developed more positive relationships with their students' families. In several cases, teachers indicated feeling greater appreciation from parents following family-school conferences. No negative effects from using the method were reported.

These teachers stated that preparation for the conferences was relatively easy. They used existing journal and group activities to help students plan. Preparation was more time consuming for kindergarten teachers. The younger children required greater encouragement to express their ideas and more support in remembering what they said. With regard to training, teachers reported a preference for school-day sessions rather than after school. And they uniformly expressed an interest in on-going training and support. As one teacher said, "I still feel like a beginner." Significantly, all of the teachers in this training group have continued to use family-school conferences.

Table 7. Sample role play scenario

Teachers are given the following information. Each teacher takes a different role in the conference. Coaching and feedback are provided as needed throughout and following the role play.

Conference participants: James, both parents, and the teacher.

Student: James, age 6, in first grade. James is a very serious child. He has asthma, which results in 2–3 days of missed school per month.

James' key points for the conference:

- I like reading.
- I like recess.
- I don't like it when kids call me "wheezer-boy."

Parents' key points (can be divided between parents as you choose):

- James loves coming to school. He hates to miss because of illness. He enjoys sharing his reading with us.
- We are worried that his asthma medication may be interfering with his ability to concentrate.
- We worry that he won't be able to use his inhaler in school as needed. Have there been any problems?

Teacher's key points:

- James is quick to cry when others tease him. He hasn't responded well to my attempts to help him ignore them.
- James is doing well academically and is picking up reading skills quickly.
- He does not always want to work independently during seatwork time.

Anecdote: James is so curious about things. He is especially interested in penguins. His ability to retain information is remarkable. He uses his computer and has pictures and information about more kinds of penguins than I ever knew existed!

They also encouraged their colleagues to participate in the training.

It is important to note that, thus far, we have evaluated the family-school conference method with only elementary school teachers who volunteered for the training. Adaptations for use with older groups of students are needed. However, because it is inconsistent with collaboration to force teachers to change their approaches to conferencing, it is anticipated that the training would only be conducted with volunteers.

Although more formal evaluation data are needed, including data from participating students and parents, it appears that the revised conferences were successful in achieving the goals of developing more positive relationships between families and teachers and assisting children in taking greater responsibility for their own learning. However, successfully implementing family-school conferences is challenging because it requires a shift in thinking that can be very difficult for teachers to master. School psychologists who elect to provide this training should expect to have an ongoing relationship with teachers in their buildings that will be beneficial to all.

Student-Led Conferences

Student-led conferences are a second alternative to traditional methods. This approach differs from family-school conferencing in that the relationship between families and teachers is not addressed directly. Instead, teachers assist students in communicating their progress to their families with little teacher involvement in the actual conferences. Student-led conferences are built on student work samples. Throughout the marking period (or year), the teacher and students designate specific work samples as "portfolio" or "conference" pieces. Toward the end of the period, both the teacher and students reflect upon the students' progress, most often in a written format. Following this period of reflection, parents are invited to the school for a conference that the student conducts. Students review their academic progress with their families and answer their questions. Parents provide specific feedback and assist with goal setting, again typically in written format. Multiple conferences occur in the classroom at the same time. At the end of the conferences, families enjoy refreshments with the teacher.

Although participants' roles differ, this approach shares with family-school conferences the goal of empowering students by increasing their ownership of the learning process. As students are encouraged to reflect upon their work and discuss it with their families, they more readily set goals for themselves and achieve at a higher level. The conferences also bring families and teachers together in a way that highlights their mutual goal of supporting student progress.

TRAINING SEQUENCE

Training teachers to conduct student-led conferences involves two primary areas: (a) assisting teachers in developing the conference format and (b) helping them prepare students (and parents) to participate. Thus, the role of the school psychologist involves presenting the conference style to teachers, guiding them through key decisions, and assisting them with the student training (e.g., helping with student role plays).

Developing the Conference Format. The actual conference process is determined by the teachers-in-training. They review relevant issues and make collaborative decisions about how they would like to proceed. Some of their decisions will hold for the entire school; others should be left open to individual teacher preferences. Some of these issues and choices are discussed below. During training, teachers should be encouraged to brainstorm creative solutions to the specific challenges in their settings.

To what extent will student-led conferences be utilized? Some teachers use student-led conferences exclusively, believing they are a major element in building classroom community (Austin, 1994). Others use a combination of traditional and student-led conferences throughout the school year (Seliner, 1997).

What types of work should be included? Many teachers focus on core academic subject areas and have their students select several papers from these areas (Seliner, 1997). Other methods include using more elaborate portfolios that focus on the student as a total learner (Austin, 1994) or developing centers that emphasize a variety of areas, including physical, artistic, and emotional development (Picciotto, 1996).

How will grades be assigned? In some instances teachers use a self-grading format in which students are responsible for establishing or negotiating their own grades. This helps demystify the grading process as students learn how grades are earned. However, this may not be a feasible choice for all teachers because of time constraints, school policy, and teacher preferences. Other teachers choose to assign grades in the traditional manner.

Who will be invited as participants? Some teachers include extended family members and siblings, whereas others invite only parents. Teachers should consider desires of the family and values of their community in addition to their own preferences when making this decision. Once these decisions are made, the school psychologist collaborates with teachers in planning preparation for students, parents, and themselves. A concrete plan for accomplishing preparations should be a primary product of the training.

Preparing participants. Students are prepared by first acquainting them with the new conference process. Austin (1994) reports that she emphasizes the importance of becoming an active learner, and that part of becoming an active learner is learning how to identify personal strengths and weaknesses. By critically examining their work, students may also increase their ability to identify learning difficulties and possible solutions.

The student's first task is to collect the appropriate materials. The teacher provides specific guidance by encouraging choices that either show the student's best work or were special learning experiences. As conference time approaches, students assemble their materials and reflect upon their progress in writing. Examples of reflective questions include: "How does this work sample reflect me as a learner?" and "What did I learn from this sample?" If self-grading is utilized, then time is needed for students to calculate their grades and discuss them with the teacher.

Practice is critical to the success of these conferences. Usually, teachers model sample conferences first and then have students practice with one another. Classroom volunteers (e.g., college students) can be used to role-play conferences. Volunteers are instructed to ask "parent-type" questions in order to help students practice (Austin, 1994).

Preparation for parents is also essential. The invitation to the conference should include a description of each participant's role. For example, while the student's role is to lead the conference, the parents' is to listen to their child and ask clarifying questions. Parents are encouraged to provide praise and feedback and to assist their child with goal setting. Parental feedback may come either before the conference, in the form of written observations of the student at home, or in reactions and responses to work presented at the conference. Austin (1994) and Picciotto (1996) provide examples of both types of feedback questions.

Teachers also need to prepare themselves. Because students lead the conferences, teachers take on unfamiliar roles as hosts and observers. Teachers avoid interfering during the conference and defer to the student when questions arise, so that students remain in the "expert" role. Teachers also must arrange the classroom in such a way that families have space to view their child's work, as well as some privacy to discuss the student's progress.

Conducting the conferences. Student-led conferences typically begin by asking the student to introduce his or her parents to the teacher. The family then sits down to review and discuss the student's materials. Particularly for the first conferences, students may need written guidelines to help remind them of the conference steps (see Table 8).

Follow-up. Teachers assess whether or not this conference style was useful for participants by providing a short survey for parents to complete after the conference (see Picciotto, 1996, and Seliner, 1997, for samples). Teachers solicit feedback from students as well, either formally or informally. They should be ready to use active listening skills during feedback sessions, because students are often excited and want to share stories about their conference experiences.

Outcome Data on Student-Led Conferences

To date, formal evaluation of the effects of student-led conferences on parents, teachers, and students has been limited to rates of participation and anecdotal reports. These data suggest that student-led conferences are successful in increasing parental participation. Conderman, Hatcher, and Ikan (1998) reported an increase in conference attendance from 35% to more than 93% of parents during the 4 years they have used student-led conferences. Picciotto (1996) noted other benefits. Parents reported learning more about their child, teacher, and school. They were often impressed by how much their children accomplished and how confident and proud the children were when presenting their work. Teachers indicated they learned more about their students and established better communication and stronger ties with students and their families. Students showed an increased awareness of their own learning styles, strengths and weaknesses, and greater motivation for goal setting. In addition, students reportedly became more responsible, taking ownership and pride in their work, and became more

active participants in their own learning (Austin, 1994; Conderman, Hatcher, & Ikan, 1998; Seliner, 1997). There may be additional benefits for students and families from non-English speaking backgrounds. Because these students led conferences in their native languages, parents learned more about their child's schoolwork than from a traditional conference.

Some limitations of this conference style have also been noted. Shannon (1997) reported that in her sixth-grade class no parents requested a traditional conference as a follow-up, but that seventh- and eighth-grade teachers did receive such requests. The reasons for these differences were not reported, but it may be that parents of the older students desired information that the students themselves could not provide (e.g., high school choices). Quiroz, Greenfield, and Altchech (1999) caution that families from some backgrounds may respond negatively to this style if it violates cultural norms of respect for elders. Thus, it is important to solicit input from families in developing the conference format and to provide choices in conference style. Because some teachers may find the preparation of students too time consuming, this style of conference may be most easily introduced in schools already using portfolio approaches to assessment.

GETTING STARTED WITH ALTERNATIVE CONFERENCE STYLES

School psychologists who are interested in collaboration are positioned perfectly to be the facilitators of change in a school, but they cannot simply go to school faculty and say, "Here's how I think you should be conducting conferences." That approach is the antithesis of collaboration. Administrative support is essential, because training will take a large proportion of professional development time and will involve families in a new way. As university trainers entering schools, we first obtain commitment from the principal and then present our ideas to the faculty. We outline a number of family-school collaborative projects they might consider, including student-led or family-school conferences, and more intensive problem-solving approaches. We describe each possibility in detail and leave it to the faculty as a group to decide which avenue they would like to explore. After a particular approach is selected, individual faculty members choose whether or not to participate in the training offered. School psychologists working within a given school as internal consultants could begin by conducting a needs assessment survey (Nagle, this volume) to determine whether and in what ways teachers want assistance in communicating with families. As noted earlier, success is more likely if faculty and consultants plan an ongoing and comprehensive set of family-school collaboration initiatives. Alternative conferencing methods may be one of these.

SUMMARY

Routine parent-teacher conferences tend to be brief, ritualized experiences that leave both parents and teachers dissatisfied and do little to encourage collaborative efforts that support student learning. This chapter provides a framework for routine conferences that highlights collaboration and empowers parents, teachers, and students. More importantly, it stresses the transformation in thinking about family-school relationships needed to successfully use the alternative styles. Considering families as true partners who are competent, caring, and capable of change opens new avenues of intervention to educators. Increasing student ownership of learning, a primary benefit of these conference approaches, fosters more satisfactory, collaborative relationships among students, teachers, and families. School psychologists who model a respectful and collaborative approach to families in their own work will be more effective consultants and facilitators of change.

Conducting these alternative conference forms requires understanding of systems theory, solution-focused approaches to intervention, and effective communication skills. These theoretical foundations are familiar to most school psychologists, making them ideal candidates to provide pre-service and in-service training to teachers interested in experimenting with new methods of conferencing.

Family-school conferences involve teachers conducting collaborative conversations with parents and students. School psychologists conducting training first introduce teachers to a different way of thinking about families and schools using the CORE model. Most of the training time is devoted to role-play practice of the communication skills and conference process. Further sessions focus on trainer feedback of the teachers' videotapes of themselves conducting actual conferences. Teachers learn to prepare themselves, parents, students, and their classrooms and to develop a flexible format to follow during the conferences. In student-led conferences, students conduct their own conferences with their parents. Training for this format involves guiding teachers through a number of key decisions (e.g., what work samples should students select, how grades will be assigned), and preparing students and parents for their participation. Multiple conferences occur simultaneously in the classroom with the teacher acting as host and observer.

The chapter closes with suggestions for ways in which school psychologists can begin exploring the feasibility of training teachers in their settings to conduct these alternative conference forms.

Best Practices in Behavioral Parent Training

Gretchen A. Gimpel and Brent R. Collett
Utah State University

OVERVIEW

Parent training is an intervention that is commonly used with families of preschool and elementary school–age children exhibiting externalizing disorders such as Attention Deficit Hyperactivity Disorder (ADHD), Oppositional Defiant Disorder (ODD), and conduct problems. Parent training may also be beneficial for families of older children as well as for families with children with other difficulties, such as depression or anxiety, and families in which abuse has taken place. Although the populations for which parent training is used are expanding, the majority of the empirical literature on parent training is still in the area of externalizing problems exhibited by young children. Parent training is one of the few psychosocial interventions with empirical support for the treatment of externalizing problems in children. A number of other treatments have been proposed for these disorders (e.g., social skills training, cognitive problem solving training), but they generally lack the consistent empirical support that parent training has received.

Parent training is unique among therapeutic interventions in that although the child is typically considered the "client" the majority of work is done with the child's parents and not directly with the child. The rationale for this approach is that by changing the manner in which parents respond to their child, the behaviors of the child will improve. Thus, parent training changes children's behaviors via changes in parents' behaviors.

Although there are a number of parent training programs used in practice and research, the general format of empirically supported programs is fairly consistent and is outlined in Table 1. As can be seen from this table, programs typically begin by teaching parents to be more responsive to their child. This is done by teaching parents to use positive reinforcement, in the form of verbal praise, for appropriate behavior as well as basic attending and listening skills. After parents have mastered this section of the program, they are instructed on the use of effective commands. Also introduced in this second segment are discipline techniques that are founded on behavioral principles, such as time out and/or removal of privileges. Thus, behavioral parent training programs are based on the concepts of presenting positives for appropriate behaviors and taking away positives for inappropriate behaviors. The positive portion of the program is conducted first to help build a positive parent-child relationship. This allows parental attention to become more reinforcing to the child and sets the stage for discipline (through the removal of positive attention) to more effectively decrease negative child behaviors (Barkley, 1997; Hembree-Kigin & McNeil, 1995). Parent training sessions typically occur once a week for about an hour and last approximately 8–10 weeks.

Parent training is often conducted in an individual format with the clinician working with one family, but treatment can also be conducted in a group format. Although the group format is likely to be most conducive to a school setting, there are advantages to the individual format (discussed later in this chapter) that school psychologists should consider. In addition, owing to the relatively short-term nature of parent training as an intervention it may be possible for

Table 1. Steps in an individualized parent training program

Part 1
- Assessment of child problems and family functioning
- Provide rationale for parent training method

Part 2
- Introduce positive attending component
- Provide description of skills and rationale for use
- Model positive attending for parents

Part 3
- Coach parents on use of positive attending
- Provide feedback to parents

Part 4
- Discuss giving good commands
- Introduce and explain use of discipline skills (time out)

Part 5
- Coach parents on use of discipline skills
- Provide feedback to parents

Part 6
- Address generalization of skills to situations outside the home

Part 7
- Promote maintenance of skills through booster sessions

school psychologists to conduct parent training with individual families.

Brief History

The parent training programs that follow the outline discussed above are largely based on original work by Hanf (1969), who first discussed the two-part parent training model that initially emphasizes positive attention followed by a focus on discipline in the form of time out. Hanf's work has been adapted by a number of others over the years, and several comprehensive parent training programs are based on her ideas (e.g., Barkley, 1997; Forehand & McMahon, 1981; Hembree-Kigin & McNeil, 1995; see annotated bibliography for an overview of selected programs). Over time, a significant amount of clinical research has been conducted on these programs. Much of this work supports the use of these programs with children, particularly those with conduct problems (Serketich & Dumas, 1996).

Patterson and his colleagues at the Oregon Social Learning Center have also had an important impact on modern parent training programs and the conceptual understanding of how those programs lead to changes in children's behaviors. Patterson's model of how conduct problems develop has been studied and cited extensively (Patterson, 1982). Through his work, Patterson has noted that children who exhibit conduct problems often have parents who demonstrate ineffective parenting strategies in response to negative child behaviors. Parent-child interactions eventually fall into a cycle of negative reinforcement, in which the likelihood of a behavior occurring is increased by the removal of an aversive. Parents give in to children's aversive behaviors (e.g., whining, temper tantrums) by removing their request that the child do something, and are subsequently reinforced by the cessation of the child's whining or tantrums. Eventually parents may withdraw from the relationship and decrease their overall monitoring of the child's behavior. At the same time, the child learns that if he or she screams or argues long enough, the parent will remove the request and the child will not have to comply. Thus, both the child and parent are negatively reinforced for inappropriate behaviors, which then escalate over time. Patterson and others have also noted that parents of children with conduct problems often exhibit a variety of other ineffective parenting practices. For example, these parents may be less supportive of their children, more inconsistent in their use of both discipline techniques and positive statements, and provide less supervision and monitoring of their children (Kazdin, 1998). Parent training programs attempt to break the coercive cycle of parenting and teach parents to reinforce appropriate behaviors and use more adaptive methods to deal with their children's inappropriate behaviors.

Importance of Early Intervention and Prevention

Parent training is often used with parents of preschool children, and early childhood is generally seen as the ideal time to intervene and prevent problems from worsening. Features of disruptive behavior disorders often emerge when children are three to four years of age and, although it was once assumed that children would outgrow these behavior problems, research suggests that this is often not the case (Loeber, Green, Lahey, Christ, & Frick, 1992). A significant portion of the children described as "hard-to-manage" as toddlers continue to demonstrate behavior problems well into early adolescence, and these behaviors often become increasingly resistant to change over time (Campbell, 1994; Eron, Huesmann, & Zelli, 1991).

Fortunately, research suggests that early intervention can prevent many of the deleterious long-term outcomes for children with conduct problems (Conduct Problems Prevention Research Group, 1999). Large-scale prevention/early intervention programs developed to date have typically included parent training as a central feature. For example, Webster-Stratton (1998) utilized a prevention model when she implemented her parent training program with groups of parents whose children were enrolled in Head Start preschool programs. The rationale for this project was to improve parents' competencies *before* children began to demonstrate clinically significant behavior problems. The results of this study suggest that the program was effective in increasing children's social competency and reducing child behavior problems. Further, most of the treatment gains observed were maintained a year after the program. Clearly, school psychologists may utilize parent training to build on parenting abilities as a preventive measure. This may be accomplished by offering these programs school-wide or targeting groups that are considered at-risk on the basis of demographic variables (e.g., low socioeconomic status).

School Psychologists As Parent Trainers

Although school psychologists may view parent training as something that is primarily done in clinic settings or by psychologists in private practice, parent training is an ideal school-based intervention. There are a number of factors that make parent training conducive to school settings including:

1. School psychologists typically have training in behavioral methods and behavioral techniques and therefore have the requisite background knowledge to conduct this type of intervention.

2. Parent training is a relatively time-limited intervention.

3. The equipment required for parent training is minimal; that is, mainly space and toys.

In addition, because externalizing disorders are some of the most common reasons for child referrals in school settings and because parent training is one of the most effective interventions for such problems, school psychologists who conduct parent training can greatly impact children (as well as their families) and their future social/emotional functioning.

BASIC CONSIDERATIONS

Prerequisite Knowledge

The empirically validated parent training programs currently available are based on behavioral principles, and are often referred to as "behavioral parent training." Assisting parents to identify appropriate reinforcers for their children, teaching parents to use ignoring to help extinguish behaviors, and helping parents implement discipline strategies to reduce inappropriate behaviors are integral to this treatment format. Thus, school psychologists planning to implement these programs should be familiar with basic behavioral principles and procedures. This includes knowledge of reinforcement strategies, extinction, and punishment procedures (e.g., response-cost, time out). Moreover, parent training requires that clinicians be able to translate their knowledge regarding these behavioral principles into terms understandable to parents.

School psychologists planning to conduct parent training should also be familiar with child development issues. This will allow them to help parents establish an appropriate set of behavioral expectations and provide interventions that are suited to a child's developmental level. Some parents may perceive their children's problems as more severe than they actually are, either because of inappropriate expectations or personal problems the parents are experiencing (Schroeder & Gordan, 1991). Thus, being able to talk to parents about what is developmentally appropriate and what they can expect from their child is important.

Appropriate Candidates

Parent training is most likely to benefit children who display noncompliant or oppositional behaviors in the home (Barkley, 1997). Specifically, parent training tends to be effective in improving parent-child relationships, increasing children's compliance with parental commands, and decreasing "acting out behaviors" such as tantrums and aggressive or destructive behavior (Barkley, 1997; Hembree-Kigin & McNeil, 1995). Behavior problems such as these are the hallmark features of disruptive behavior disorders (i.e., ADHD, conduct problems, Oppositional Defiant Disorder), and, as noted above, much of the research on parent training has focused on this domain. However, addressing these issues may be beneficial in treating any number of specific disorders and child behavior problems (e.g., child depression, anxiety, developmental delays, adjustment problems) (Barkley, 1997; Hembree-Kigin & McNeil, 1995).

Most of the programs currently available have been designed for children between the ages of 2 and 12 years (Barkley, 1997). Obviously, there are considerable variations within this age range, and it is often necessary to adjust programs so that they are appropriate for an individual child's developmental level (Forehand & Wierson, 1993). For example, while time out procedures are quite effective for young children, the duration of time out should be modified as a function of a child's age (i.e., shorter time-out intervals for younger children). Time out may not be appropriate for older children (e.g., older than 10–12), and may need to be replaced with alternative discipline procedures.

Although parent training may be a useful intervention for very young children and for adolescents, use of such programs with these populations would likely require substantial modifications. With young children (i.e., children as young as 18 months old), modifications would likely need to be made to accommodate a parent training program for their receptive language abilities. A behavior that may be labeled "noncompliance" in an older child may simply reflect a young child's failure to understand or inability to comply with a parental command. Similarly, parent training programs for use with the parents of older children and adolescents require significant modifications. At this developmental level, it becomes increasingly appropriate for adolescents to be included in decisions regarding behavioral expectations and consequences for appropriate and inappropriate behavior. Barkley, Edwards, and Robin (1999) have published a manualized treatment program (*Defiant Teens*) for use with this population. In their program, parents are encouraged to develop a behavior contract with their adolescents that clarifies behavioral expectations and consequences. Additional components are included to encourage parents and adolescents to solve problems in a collaborative manner and to communicate more effectively.

Parent-specific factors may also influence the efficacy of parent training and the likelihood that parents remain in treatment, and should be considered when determining whether or not a given child is likely to benefit from parent training (Kazdin, 1993, 1997). Some of the parent-specific factors that have been shown to influence the effectiveness of these programs include

1. Socioeconomic status

2. Parental psychopathology (e.g., maternal depression, stress)

3. Parental marital problems

4. Low social support

In addition, as with most interventions, motivation plays a prominent role in the success of parent training. While some parents are quite willing to participate in parent training and modify their parenting practices, others may view this as an insult to their parenting. Such parents often want the clinician to "fix" their child, since "the child is the one with the behavior problem." When presented with the rationale for parent training in a positive and enthusiastic manner, parents often become more engaged in this approach. However, some parents may continue to be resistant, thus making it necessary to pursue other treatment options.

Although parent training has been demonstrated to be effective as a primary or sole treatment, it often becomes apparent that additional services are required to adequately address the needs of children and their families. For example, it may be appropriate for school psychologists to refer a child's parents for outside services (e.g., marital counseling, individual therapy) in addition to continued participation in parent training. These additional services may serve to address the needs of a child's family more fully and often increase the success of the parent training program (Dadds, Schwartz, & Sanders, 1987; Webster-Stratton, 1994). Similarly, children may also need additional services (e.g., medication, classroom management programs, social skills interventions). Although some research suggests that treatment gains achieved during parent training generalize to other settings including school (McNeil, Eyberg, Eisenstadt, Newcomb, & Funderburk, 1991), this is not always the case (Kazdin, 1993). Thus, while parent training can be effective when used alone, it is often desirable for school psychologists to view this as one component in a more comprehensive treatment package.

Group Versus Individual Parent Training

Both group and individual parent training programs have been demonstrated to be effective, and both present unique advantages and disadvantages. Research conducted to date suggests that these two approaches are roughly equivalent with regard to efficacy and parent satisfaction (Serketich & Dumas, 1996; Webster-Stratton, 1984). Thus, the decision to utilize a group versus individual format is often dependent upon clinical judgment and pragmatic constraints.

Carolyn Webster-Stratton and her colleagues have compiled an impressive body of research involving group parent training utilizing videotaped models. Her findings suggest that these programs are quite effective and well accepted among parents (Webster-Stratton, 1984,1994; Webster-Stratton & Hammond, 1997). Advantages of the group parent training format noted by Webster-Stratton and others include

1. Cost effectiveness (e.g., Webster-Stratton (1984) showed group programs to be five to six times as cost effective as individual programs)

2. Opportunities for parents to benefit from the experiences of other parents also dealing with child behavior problems

3. Chance for socially isolated parents to interact and receive support from others

Although group programs have a number of benefits, they also present some limitations and drawbacks including

1. Parental feelings of reticence to actively participate owing to concerns others in the community will learn of their child's behavior problems or discomfort sharing information about their parenting practices

2. Inability of clinicians to adequately address needs of parents who have children with unique behavioral problems

3. Limited opportunities for parents to practice using behavior management techniques in session with clinician feedback

The advantages and disadvantages of individual parent training are essentially the inverse of those listed above. Without question, these programs are more time-intensive and, therefore, are generally more costly. However, individual parent training does provide a number of benefits not readily attainable through group parent training including

1. Psychologists can tailor an intervention to the needs of an individual child and family

2. Psychologists have opportunities to observe interaction patterns and parenting practices

3. Parents have numerous opportunities to practice using behavior management skills in session

4. Psychologists can observe parents' use of new skills and provide corrective feedback when necessary

Facilities/Equipment

It is generally helpful to begin with a manualized treatment protocol and make adaptations for individual families as needed. These manuals often contain parent handouts that can be photocopied, thus negating the need for clinicians to develop their own handouts. In addition, most manuals provide a rationale for the use of parent training and in this context provide helpful ideas for rationales that can be provided to parents. Having a manual is particularly important for a professional who is relatively inexperienced in conducting parent training but can still be helpful for those with more experience. Several manualized treatment programs are referenced and discussed in the annotated bibliography for this chapter.

Although many of the parent training programs discussed in manuals and in the literature were originally developed for use in clinic settings, these services can easily be provided in community-based facilities. In fact, some research suggests that community-based facilities such as public schools and community centers are advantageous in that they seem more accessible to minority families and families of children with more severe behavioral problems (Cunningham, Bremner, & Boyle, 1995).

Group parent training, which is more common in community-based facilities, obviously requires a facility with adequate space and seating for a group of adults. Parent attendance at group meetings is facilitated if child-care services can be provided onsite. Attendance is also encouraged if refreshments (i.e., snacks, beverages) or small incentives are provided. Group parent training programs often use videotaped models of appropriate parenting strategies and therefore require a television and video equipment. Videotaped materials can be purchased through several publishers along with additional resources (e.g., treatment manuals, parent handouts), and these are helpful for both group and individual programs.

In individual parent training, the referred child is included in treatment and is present for many of the sessions. Because much of the practice of skills takes place within a play-based context, a range of toys appropriate for children of various ages is helpful. It is often recommended that clinicians providing individual parent training observe parent-child interactions, either during structured activities or unstructured play, through a one-way mirror. These observations can provide critical information about interaction patterns that contribute to a child's behavior problems and serve as a useful tool in evaluating treatment progress (Hembree-Kigin & McNeil, 1995). An additional tool that is sometimes recommended is the "bug-in-ear" device. This includes an earpiece that parents wear during interactions with their child and a microphone that the clinician uses to communicate with the parent while observing behind a one-way mirror in another room. Although it is possible to conduct similar observations with the clinician in the room, child behavior may be influenced by the therapist's presence and this may not reflect an accurate sample of naturalistic parent-child interactions (Hembree-Kigin & McNeil, 1995).

Obviously, practitioners working in the schools typically do not have access to one-way mirrors and sophisticated microphone equipment. However, that should not discourage school psychologists from using an individualized parent training program. It is quite possible to conduct effective individual parent training with minimal resources. With access to a private room that contains chairs and a table and a small variety of toys, parent training can easily be conducted in the school setting. Instead of observing parents through one-way mirrors and providing feedback from out of the room, the school psychologist will simply be present with the parent and child and provide direct coaching and feedback to parents on their use of the learned skills.

BEST PRACTICES IN PARENT TRAINING

Before Beginning Parent Training

Before beginning parent training, the school psychologist should ensure that this intervention is appropriate for the presenting problem and that it has a high likelihood of success. Thus, an assessment of the presenting problem (including operationally defining the behaviors of concern) and of the family situation and dynamics should be the first step. As mentioned earlier, there is a great deal of empirical support for parent training, thus, it should be considered as a treatment option whenever a young child presents with externalizing behavior problems (e.g., noncompliance, temper tantrums, aggression). The practitioner also needs to take into account the parent specific factors described above before settling on parent training as the intervention of choice. Thus, the assessment phase may include not only information on the child but also information about the family environment and the parents' mental health status. Below are areas typically covered in assessments along with examples of questions or instruments that may be used:

1. Parent interview regarding the child's development, past problems, and current behaviors of concern
   - Describe behavioral difficulties at home and school.
   - How does child get along with peers/siblings?
   - Any major developmental problems, illness, accidents, etc.?
   - Has child ever received therapy before? If so, for what?
   - What does child do well or like to do?

2. Parent interviews regarding current discipline practices
   - Who ordinarily disciplines child?
   - How is child disciplined?
   - What is most effective? What is not effective?

3. Parent interview regarding family dynamics, marital problems, etc.
   - What is the home schedule of mother/father?
   - Has either parent received therapy?
   - What is the level of marital satisfaction?
   - How is child's relationship with mother/father?

4. Norm-referenced measures of a child's behavior
   - Child Behavior Checklist (Achenbach, 1991)
   - Behavioral Assessment System for Children (Reynolds & Kamphaus, 1992)
   - Disruptive Behavior Disorders Rating Scale (Barkley, 1997)
   - Home Situations Questionnaire (Barkley, 1997)

5. Informal behavioral observations during the interview of the parent-child interaction

Clinicians may also want to consider:

1. Measures of parent functioning (e.g., the Symptom Checklist 90—Revised, a measure of adult distress and psychopathology (Derogatis, 1983)

2. Measures of parent child interaction (e.g., the Parenting Stress Index) (Abidin, 1995)

3. Formal observations of the parent and child interacting using a system such as the Dyadic Parent-Child Interaction Coding System (see Hembree-Kigin & McNeil, 1995)

4. Classroom observations of the child

Once it is determined that the child and family are good candidates for parent training (e.g., child is young and exhibits acting out behavior, parent has no major psychopathology), the parents should be provided with a rationale for the use of this technique. Many parents who seek psychological services for their children may expect that the professional will meet individually with the child and that they, as the parents, will be only minimally involved in treatment. Providing a description and rationale for the use of parent training up front can help prevent confusion about services. In addition to emphasizing the effectiveness of this technique, clinicians should emphasize the role the parents play in the child's behavior. It is important not to blame the parents for the child's current behavior problems, but to relay the message that the parents' behaviors and response to their child can greatly affect the behaviors exhibited by the child.

Once the program has been explained to the parents and their questions answered, the intervention begins. If the child is from a two-parent home then it is ideal to have both of the child's parents involved. However, this is often not feasible because of scheduling problems or lack of interest on the part of one parent. If this occurs, then the clinician should encourage the attending parent to discuss techniques learned in session with the child's other parent. When only one parent attends, it is typically the mother. Although this is clearly not ideal, a review of paternal involvement in parent training (Horton, 1984) suggests that inclusion of the father does not provide clear benefits over conducting parent training with the mother alone. This review, though, is now dated, and as fathers are increasingly taking more of a role in childrearing, this may change. In addition, Horton does note that the general marital relationship as well as the father's support of the mother as she goes through the program are likely important.

Basics of Parent Training

Almost all parent training programs that focus on externalizing problems such as ADHD and conduct problems, follow Hanf's (1969) two-stage model described earlier. Although the positive reinforcement portion of the program is typically presented first, there may be situations in which the school psychologist would want to first cover the discipline component. For example, with children who demonstrate extreme levels of aggression reversing the order may be warranted (Hembree-Kigin & McNeil, 1995). Although there is little empirical research on the effects of ordering of treatment, at least one study (Eisenstadt, Eyberg, McNeil, Newcomb, & Funderburk, 1993) found that children improved regardless of the order of treatment stages.

During parent training four steps are followed in teaching the skills at both stages of the program:

1. Skills are didactically taught to the parents
    - Skills are verbally explained to parents
    - Parents are provided with handouts describing skills and given examples of techniques to be used

2. Skills are modeled
    - Clinician models skills with referred child *and/or*
    - Videotaped models used

3. Parents practice the skills in session and receive therapist feedback on their performance
    - Parents practice with their child *or*
    - In groups, role plays conducted with other group members

4. Between sessions parents practice learned skills at home and monitor their progress
    - Parents keep a written record of whether the skill was practiced
    - Parents note any difficulties they had using the skill

The feedback or coaching of the parents, which often takes place over multiple sessions, is an important part of the training and something that may be particularly difficult for beginning therapists (Hembree-Kigin & McNeil, 1995). Coaching can help parents correct problems immediately as well as help parents problem solve regarding child-specific issues and provide confidence to parents as they implement the learned skills. Additionally, directly assessing parent progress is important because parents are often not accurate reporters of their skill level and the problems that they are experiencing as they use the skills at home (Hembree-Kigin & McNeil, 1995). Further, parents may use a skill in what they believe is the appropriate manner when in actuality their use is not completely correct and is hindering their success.

Providing Attention/Praise/Positive Reinforcement

In the positive attention phase, parents are taught to provide attention and praise for positive child behaviors. Unfortunately, many parents of children with behavior problems neglect to attend to their children's appropriate behaviors. Parents often respond only to the most salient behaviors the child is exhibiting, which tend to be the negative behaviors. When the child is behaving appropriately, parents often fail to attend to this and assume that it is better to "leave well enough alone." Unfortunately, this creates an interaction in which the child is only receiving attention for negative behaviors, and, thus, these are the behaviors likely to increase (Patterson, 1982). Teaching parents to provide attention to positive behaviors not only increases the likelihood that these behaviors will increase in frequency but also is important as it helps teach the child what *to do*. Working only to eliminate negative behaviors serves only to teach the child what *not to do* without developing a repertoire of appropriate behaviors.

In most behavioral parent training programs, these positive skills are taught and practiced in the context of a play situation, sometimes referred to as the "Child's Game" or "Time-in" to reflect the positive, child focused aspect of this part of the program. For this activity, toys that can be used in a constructive manner are needed. Such toys include crayons and paper, Legos, Tinker-Toys, and wooden blocks. Toys that require little interaction between the parent and the child (such as most video games) or have structured rules (such as board games) are not appropriate. In addition, toys that are likely to promote aggressive play (e.g., army figures, toy guns) are not suitable for these activities. During this play context, parents are instructed to

1. Describe what their child is doing

2. Reflect verbal statements their child makes

3. Praise their child for appropriate behaviors

4. Ignore minor misbehaviors

5. Issue no questions, commands, or criticisms

These expected parent behaviors are similar across different programs and detailed descriptions and examples of each of the above can be found in most parent training manuals (e.g., Barkley, 1997; Hembree-Kigin & McNeil, 1995).

As with the introduction to parent training in general, it is important to provide parents with a rationale for the use of this positive play time. This rationale might include the following (Barkley, 1997; Hembree-Kigin & McNeil, 1995) points:

1. Positives can increase desired behaviors

2. Positives help teach the child what parents like and expect the child to do

3. Positives set the stage for a more positive and enjoyable parent-child relationship overall

4. Positives may help increase the child's self-esteem

Once the "Child's Game" has been explained and modeled for parents, they practice the skills in the session. It is important to acknowledge to parents that although this activity sounds easy to do, it really is not. In particular, parents frequently have a hard time avoiding questions and often feel silly or unnatural interacting with their child in this context. As parents practice these skills, the therapist provides feedback on the use of the skills as well as other factors that may impact the parent-child relationship. For example, when parents first learn these skills it is not uncommon for them to talk in a monotonous, unenthusiastic manner. It is important that parents be enthusiastic and positive in their tone of voice, as well as in what they say. Children are adept at picking up on parents' lack of genuine interest, which then undermines the whole premise of this positive time.

In addition to practicing these skills in session, parents are asked to practice at home by setting aside anywhere from 5–20 minutes each night to engage in this play activity. Different authors have differing recommendations on the amount of time parents should spend engaged in this activity at home. For example, Barkley (1997) recommends 15–20 minute sessions while Hembree-Kigin and McNeil (1995) recommend 5 minutes. No empirical guidelines exist to suggest whether longer times lead to more effective learning of the skills, but much research supports programs which use the 5 minute play time. Thus, it seems likely that 5 minutes is a sufficient amount of time. Further, setting the practice time at 5 minutes may serve to increase parent compliance with this practice. Of course, there is nothing wrong with the longer time either but parents are encouraged to be consistent and to make a commitment to set aside the same amount of time each night for these sessions. It is important that as the parents practice at home, one parent practices with one child. Ideally, if both parents are in the home, then both would practice these skills. Parents may apply these skills to other children at home in addition to the referred child but should make sure they practice with each child individually.

Commands/Discipline

Once parents have mastered the positive attention component, they are taught to give clear, specific, and appropriate commands. Commands should be given one at a time and should be stated as directives rather than questions or suggestions. Parents should also ensure that the child is physically capable of following through with the command (Hembree-Kigin & McNeil, 1995; Schroeder & Gordon, 1991). Once they learn to give appropriate commands, parents are taught to follow up on these commands with either positive reinforcement for child compliance or a consequence for noncompliance. Time out is the most often used consequence for non-compliance and is generally quite effective with younger children.

As with teaching the positive skills it is important that these discipline skills be modeled for parents and that they have the opportunity to practice these skills in session. Particularly with time out, parents often report that they use this technique but that it does not work. Most frequently this is because the parent is not using the technique in an appropriate manner. Common mistakes parents make when using time out include:

1. Continuing to talk to their child while the child is in time out (thus negating the time out or time away from attention aspect of this technique)

2. Leaving the child in time out for excessively long periods of time

3. Not staying close by to insure that their child remains in the time out location

Although it is not always possible to get a child in time out in the therapy session, this is the ideal so that parents can be coached through their first use of time out and problems can be dealt with in session (Hembree-Kigin & McNeil, 1995).

Time out may not be appropriate for older children, and some other discipline strategy may need to be implemented. Contingency contracting, either through a comprehensive token economy system (such as that discussed by Barkley, 1997) or a simplified response-cost system, is commonly used. In such a system, parents list the privileges children can earn for appropriate behaviors and the privileges that will be taken away for inappropriate behaviors. Another technique that may be used with older children is "job card grounding" (Christophersen, 1988). When using this technique, children are not allowed certain privileges until they complete brief chores (e.g., dusting the furniture in the living room, sweeping the kitchen floor). Thus, the actual time the child is "grounded" is kept to a minimum and is easier for parents to enforce. In addition, the child has control over the length of time grounded. If the child completes the job(s) immediately, then the grounding lasts only a short time. If the child does not complete the job(s) immediately, then the grounding will last considerably longer.

Promoting Generalization/Maintenance

Once parents have mastered the basic skills, it is important to help them implement these skills in situations outside the home. Public places such as stores and restaurants provide unique challenges to parents and should be addressed during parent training. Most parent training programs offer some guidance on how to deal with these problems. Parents are typically instructed to develop rules for situations ahead of time as well as incentives for appropriate behavior and discipline techniques for inappropriate behavior. Time out can be used in public, but it is important to ensure that parents have mastered time out at home before having them use this technique outside the home.

As was noted earlier, behavioral improvements seen in the home after parent training often do not generalize to other settings. To help promote generalization, school psychologists conducting parent training may want to consider building a school component into their program. This could be done in a number of different ways including

1. Providing similar training to teachers in a group format over a series of in-service training sessions

2. Consulting with the individual child's teacher on a regular basis and helping the teacher develop a parallel program adapted to the classroom setting

3. Using a home-school note system in which performance on target behaviors at school are tracked by the child's teacher(s) on a written form (e.g., Kelley, 1990), which is then taken home at the end of each day where parents provide consequences for meeting behavioral goals or not meeting these goals

Of the above solutions, the home-school note system is the only one that encourages active communication between the parents and the school. In this system parents are informed on a regular basis of what is happening at school, and they are involved in remediating problems there as well as at home. Thus, if increased school-home collaboration is a goal of treatment, this program should be considered.

In addition to helping parents generalize the skills they have learned, school psychologists should build in a system to help parents maintain skills. One option is to continue having brief meetings with parents on a regular basis (monthly or bi-monthly) so that skills can be reviewed and any problems parents may be having can be addressed as needed. Unfortunately, there is little empirical research regarding the best way to promote maintenance of treatment gains or what factors contribute to the maintenance of gains (Eyberg, Edwards, Boggs, & Foote, 1998).

Addressing Parent Issues

As was noted earlier, most parent training programs do not specifically focus on parent problems (e.g., marital distress, depression). However, parental issues can greatly impact the parent-child relationship, and, thus, directly focusing on these issues may increase the overall effectiveness of a parent training program. There are a limited number of studies that have found support for the idea that general parent training by itself can decrease parental stress and improve parental efficacy/self-esteem (Anastopoulos, Shelton, DuPaul, & Guevremont, 1993; Pisterman et al., 1992; Schuhmann, Foote, Eyberg, Boggs, & Algina,1998). Whether parent training has an impact on more severe parent problems, such as depression or marital problems, is less clear. Studies looking at families with marital problems (Dadds, Schwartz, & Sanders, 1987) and maternal depression (Chronis et al., 1999) found that specific components to address these issues were needed and that parent training alone was not enough to alleviate these problems.

Although in a clinic setting, a psychologist may provide add-on components that address parental issues specifically, it is unlikely that this would occur in a school setting. School psychologists who are providing parent training and realize the parents are struggling with issues not adequately addressed through parent training should refer these parents to psychologists in the community. These additional services may provide more benefits to the family as a whole and may help prevent premature termination of parent training (Kazdin, Mazurick, & Bass, 1993; Prinz & Miller, 1994).

Adapting for Group Training

Although the above information has been presented primarily in the context of conducting parent training with individual families, as mentioned earlier parent training can also be conducted in a group format. The concepts that the parents learn in group training and the manner in which these concepts are taught is very similar to what occurs in individual parent training. The main differences relate to the child not being present. Thus, the modeling and practicing of skills is not conducted directly with the child but through other methods such as videotapes and role plays. In addition, clinicians need to be aware of group dynamics and ensure that all parents are actively involved in discussions and role plays.

Webster-Stratton's videotaped-based program mentioned above is one of the most well-researched group programs (Webster-Stratton & Hancock, 1998). This program follows the same outline as that described for individual parent training in terms of teaching positive attending skills through a play context and then teaching discipline skills. Webster-Stratton has also developed a companion program that focuses more on parental issues (e.g., coping skills, problem solving, communication, anger management) which addresses some of the family / parent issues discussed earlier. The addition of this component has been found to produce additional benefits for participants, particularly on measures of parent behaviors, when compared to the basic parent training program (Webster-Stratton, 1994).

When using group parent training, Webster-Stratton has found that programs including videotape models are superior to group instruction without the videotapes (Webster-Stratton & Hancock, 1998). Thus, clinicians conducting group programs should consider the addition of videotaped models that allow parents to see examples of the skills in use. Webster-Stratton also incorporates role-play exercises in her program, thereby allowing parents to have some experience practicing the skills and receiving feedback on the skills prior to using them at home with their children. Homework, in the form of parents practicing the skills and reading materials related to what is being learned in session, is also assigned on a regular basis. In addition, some follow up with the parents individually, such as occasional phone calls that Webster-Stratton recommends, may be beneficial and help clinicians track progress of parents who may be less involved in group sessions.

SUMMARY

Parent training is an effective short-term intervention for use with families with children exhibiting disruptive behaviors. Although parent training is often discussed as an intervention for use in clinical settings, parent training can easily be conducted in school settings, and these settings may be particularly conducive to group parent training. As school psychologists continue to expand their roles in the schools and become more involved with the provision of mental health services, it is likely that parent training will become an intervention increasingly used in the schools.

Particularly in elementary schools, many referrals for mental health problems involve externalizing problems. Because these are the disorders that are most conducive to parent training, school psychologists should strongly consider the use of this intervention for these referrals. It is also important to intervene early, and school psychologists should not assume that behavior problems exhibited by young children will improve without intervention. Although classroom-based interventions may seem more manageable, to have the maximum impact and improve the long-term outcomes for the child working with the parents is of utmost importance. Child behavior problems are often exacerbated by unhealthy parent-child interactions, and if this pattern is not broken, then it is unlikely that the child's behavior will improve.

When conducting parent training, school psychologists should keep in mind that the model presented in this chapter, involving teaching parents to use behavioral principles in the form of positive reinforcement and punishment (response cost), have the most empirical support. Thus, it is recommended that school psychologists use a program based on these principles. It is important, though, that psychologists buy into and believe in the principles used in these programs. Otherwise, it is likely that they will be ineffective in their presentation of such techniques. Psychologists should also transfer this basic behavioral knowledge to parents as they are describing the skills involved in the program. Parents should not simply be taught how to reinforce and how to discipline, but should also learn the rationale behind the use of these methods. Parent training is more than technique teaching. It is intended to give parents a better understanding of the parent-child relationship and the factors that contribute to that relationship. This understanding, along with the techniques, will have a lasting impact on parents and their children.

Schaefer (Eds.), *Handbook of Parent Training: Parents as co-therapists for children's behavior problems* (2nd ed.) (pp. 98–152). New York: Wiley.

ANNOTATED BIBLIOGRAPHY

Barkley, R. A. (1997). *Defiant children: A clinician's manual for assessment and parent training* (2nd ed.). New York: Guilford.
This manual provides a comprehensive description of Barkley's parent training program. The manual begins with background information on noncompliance/defiance and the associated problems of children and their families as well as assessment of defiant children. A step-by-step description of the parent training program is then provided. The description of each step begins with an overview of the goals for the session, the material required, an outline of the topics to cover in session, and the homework for the parents. Following this, a detailed description of the session is provided. Also included in the manual are forms that can be photocopied. These include assessment measures as well as parent handouts for each step of the program. A Spanish supplement of this manual is available that contains Spanish translations of the assessment materials and parent handouts.

Barkley, R. A., Edwards, G. H., & Robin, A. L. (1999). *Defiant teens: A clinician's manual for assessment and family intervention.* New York: Guilford.
The program described in this manual is an upward extension of Barkley's Defiant Children program described above with the addition of "problem-solving communication training." There are 18 steps in this program with the first 9 steps being direct adaptations of the Defiant Children program and the last 9 steps focusing on "interpersonal skills needed by the parents and teen to develop better conflict resolution" (p.79). As with the Defiant Children program, handouts for parents (and in some cases for the adolescent) are included in the manual, and these can be photocopied.

Briesmeister, J. M., & Schaefer, C. E. (Eds.). (1998). *Handbook of Parent Training: Parents as co-therapists for children's behavior problems* (2nd ed.). New York: Wiley.
This book is an excellent resource for those interested in the use of parent training across a number of different problems. Each of the 17 chapters discusses the use of parent training with a specific population, and each chapter is written by an expert in that area. In addition to chapters on externalizing behaviors (e.g., ADHD, conduct problems) there are also chapters on internalizing disorders (separation anxiety disorder and school refusal) as well as other disorders (e.g., enuresis, developmental disabilities, sleep problems).

Hembree-Kigin, T. L., & McNeil, C. B. (1995). *Parent-child interaction therapy.* New York: Plenum.
This book provides a detailed description of parent-child interaction therapy (PCIT), as developed by Sheila Eyberg. The first chapter of this book discusses the foundations of PCIT, and the remaining seven chapters are devoted to detailed descriptions of the steps in the program. In their descriptions of the program components, the authors provide a great deal of information in terms of what to actually do with parents and say to parents in sessions. Their examples from their own experiences in conducting PCIT are helpful. Included in the appendix of this book are assessment measures that they use when conducting PCIT as well as parent handouts on each step of the program.

Webster-Stratton, C., & Hancock, L. (1998). Training for parents of young children with conduct problems: Content, methods, and therapeutic procedures. In J. M. Briesmeister & C. E. Schaefer (Eds.), *Handbook of Par-*

ent Training: Parents as co-therapists for children's behavior problems (2^{nd} ed.) (pp. 98–152). New York: Wiley.

This chapter describes Webster-Stratton's videotaped-based parent training program. Information on the effectiveness of the program is presented followed by descriptions of both her BASIC parent training program and her ADVANCE parent training program. Included in this chapter is a discussion of videotape models and their use in parent training sessions. More information on this program (including information on ordering the manuals and videotapes used in this program) can be found at the following website: www.incredibleyears.com.

Charter Schools, School Psychologists, and the Potential for Best Practice Implementation

Caven S. Mcloughlin, Melissa Lewis, and
Carrie Hutchinson
Kent State University

OVERVIEW

Unlike many chapters on school psychologists' responsibilities for enhancing school-based best practice, this contribution focuses in large part on understanding the means used by charter schools (sometimes called "community schools") to ensure student success, along with the motivations of those who patronize them. One purpose is to introduce a movement with powerful allies that is gaining broad acceptance so as to better understand the forces that have relevance for *any* school undergoing reform. A further purpose is to identify potential niches that might be served by school psychologists within the charter movement even at this relatively late stage in the movement's development.

Since many parents are finding charter establishments the more appealing among their school choice options, all educators, *especially those serving public schools*, have a professional obligation to investigate this growing phenomenon. The successes wrought by charter arrangements may contain valuable lessons for public school psychologists who aim to garner broad base parent support. And the employment opportunities for school psychologists can only be enhanced through contemplating whether there is a complementary role for school psychologists in this sector of "independent education."

School psychologists have not broadly endorsed the educational reforms being promoted under the aegis of charter education. There are more unanswered questions about the role of the school psychologist in charter education than there are answers. There is almost no established empirical support for wide ranges of disparate educational practice that are being incorporated into such schools. In a profession bounded by a reliance on decision making that is grounded in empirical support, school psychologists have largely taken a wait and see approach to implementing alternatives to the traditional public model. This is entirely understandable in light of the fact that the charter philosophy allows charter operators to selectively engage only the services of professionals they view as significant to their own educational establishment. Few charter operators currently seek out school psychologists as problem solvers for their schools except where mandated as part of the special education program requirements.

School psychologists have yet to craft a clear role or vision for providing service to the charter education movement. The very nature of charter schools as an alternative to the standard system encourages a hands-off approach by a group of professionals almost exclusively employed, from a historical perspective, in the public domain. In fact, few school psychologists have accepted leadership in shaping the alternative school reform movement and as a consequence relatively few niches have been carved for school psychological services or mental health professionals.

To date, school psychology's role toward the independent schools movement has largely been *reactive* to changes imposed by circumstances crafted by political entities marginal to the educational mainstream. This avoidance of direct involvement mirrors the distance that some educator-unions intentionally imposed when charter schools were mooted, the widely accepted logic being that if left to survive on their merits the charter schools would fail and the status quo would return by default. In their case, the rationale for non-involvement was the lack of supporting evidence for this alternative approach, and proprietary concerns about hiring practices and flexible licensure requirements for professional staff.

These concerns remain largely unaddressed; that is, there is still almost no data set endorsing charter education as a viable educational alternative *on its merits*, and charter establishments continue to hire individuals without formal qualification in critically important positions guiding children's education. Nonetheless, it was hardly imagined that charter education would catch the imagination of a section of the nation's parents and become the fastest growing segment in contemporary educational service.

The window of opportunity for school psychology to have an influence on the organization, goals, and procedures in charter education is fast closing. Business entities, including those founded on the profit principle, have already honed their business/education model for franchised charter establishments. School psychology is never or only rarely included. Nonetheless, the Achilles heel for the charter movement is demonstrating satisfactory progress toward their agreed goals; that is, the standards of the charter against which they must perform. The quality of data yet available to support any contention of superior quality education from charter establishments is speculative, faith-based, and largely anecdotal. So far, this quality of information has sufficed. Should harder data be required to convince State Boards of Education or other governmental agencies of the viability of the charter model, then their proponents will need to turn to professionals with the research skills common in school psychology. Accountability studies may become the entry point for school psychology, rather than expertise in special education service provision.

What are Charter Schools?

Charter schools are publicly funded, non-sectarian schools that operate free of the many regulations, restrictions, and mandates of traditional public schools. Charter schools operate as separate legal entities designed and operated by educators, parents, and community members. They comprise one of the fastest growing "alternative education" service options (exceeded only by home schooling). Almost universally, parents who send their children to charter schools say they are seeking a better educational experience. In a majority of cases, these parents are dissatisfied with the public school system but cannot afford the route of a private or religious-foundation school. The draw of a charter school is that it is funded by public money, but does not have the same constraints as a public school. Charter schools also may offer a greater variety in curriculum for children who have been unsuccessful in the public school districts and are perceived to have been held back by an inflexible traditional system.

Many reports have identified the availability of *options* as the factor making charter schools appealing to parents. The important question is *why*? What is it that makes parents and other educators want to embrace this alternative education movement? While voluminous research points to individualized education as being successful for many children who have experienced failure in the mainstream, the major issue is what makes this particular alternative option so successful? Many skeptics say that the reason for the success is that alternative schools lack adequate demands for accountability. Accountability, the measures used to demonstrate success, is thus an important issue to consider.

This chapter considers the following issues: Factors that make charter schools appear successful; accountability in the presence of autonomy; characteristics of charter school students, particularly those with disabilities; and the foci, interests, and motivations of both parents and administrators who choose this route to an alternative education. Many misconceptions concerning charter schools exist because most public school educators live and work in an entirely different arena, and these misconceptions are also addressed. The role of the school psychologist in charter school service is only indirectly addressed because there are so few examples on which to draw. The reader should contemplate a potential role—typically one yet undefined—for professional school psychology in the service of charter schools.

BASIC CONSIDERATIONS

What is a Charter School and Why are They Established?

Charter schools are independent, but public, schools that operate under a time-limited contract between the school's developers and a sponsoring organization, typically a local education authority, school district, or a state school board. Charter schools are similar to other public schools in that they are funded through the state, subject to federal law, and are nonsectarian, tuition-free, and prohibited from discriminatory student admission procedures. However, it is at this point where the similarities end. The major difference between a charter and a traditional public school is that a charter school is an independent legal entity that has autonomy over every aspect of its own operation. In exchange for this self-determination, charter schools are held accountable for meeting the educational goals that are written into their charter, and freed from rules but ostensibly accountable for results (Bierlein, 1997; Manno et al.,1998a; Manno, Vanourek, & Finn, 1999; Nathan, 1996; U.S. Department of Education, 2000). In summary, charter schools are generally free from the bureaucratic controls imposed by a locally elected school board, free to decide what to teach and how to teach it, free to decide whom to hire and how to deploy resources, free to decide what hours to operate and how best to meet the needs of its student body, and yet are funded from the public purse.

In 1989 Ray Budde authored *Education by Charter: Restructuring School Districts* (Budde, 1989). In this book he named and defined the charter school concept, and in case study format followed a new superintendent who provided school board members and staff with a vision of how to restructure a school district over a decade. The impetus started with a gradual shift of the "responsible control" for the entire function of instruction to those who teach. The school board accomplished this shift by granting 3- to 5-year "charters" to educators who were organized according to subjects, grade levels, and schools.

Shortly after Budde's 1989 publication, Albert Shanker received national recognition for popularizing an understanding of charter schools through speeches to Washington media groups and through *New York Times* articles. He called on teacher unions and local school boards to endorse the charter movement and celebrate innovation in educational instruction and programming. However, his call fell on the deaf ears of the membership of teacher "associations" skeptical about the inclusion of individuals without formal teaching credentials, management by non-educators, salary based on results, the availability of a for-profit motive, and the failure to include tenure protections in charter establishment employment contracts.

The modern charter school movement began in earnest in 1991 when Minnesota enacted the nation's first charter school law. Since that time, 36 states and the District of Columbia have adopted charter school legislation, and 32 states have opened charter schools. Charter schools are a rapidly developing sector of the educational services options, having grown to approximately 1,700 schools that enroll some 350,000 students, and accounting for approximately 1% of all public school students within those states operating charter schools. Public demand for charter schools has not been satiated, and 7 out of 10 charter schools report that they have waiting lists (U.S. Department of Education, 2000; Charter Friends National Network, 2000).

Educators, parents, and organizations (both profit and non-profit entities) have founded charter schools. In general, founders share a frustration regarding the confines of the traditional public school system. Specifically, founders of charter schools say that they develop their schools to "realize an alternate vision for schooling" (75%), "for autonomy" (17%) and "to serve a special population" (30%) (U.S. Department of Education, 2000). The motivations include

1. A passion to serve children's educational needs with novelty and unfettered access to innovation.

2. A desire to reflect in the educational curriculum the tenets, beliefs, history, and content-specific analogies drawn from a particular racial, ethnic heritage (often called an "ethnic-charter").

3. A wish by disaffected educators to try another way to get their message across to students (a "conversion charter").

4. A profit motive—typically by those individuals aiming to capitalize on their identification of perceived wasteful procedures in the time-honored public model.

5. A need expressed by disgruntled parents dissatisfied with the current public alternatives (Schneider, 1999).

For parents, the allure of charter schools is the prospect of having a non-fee–based alternative to a traditional public school system, a system typically perceived as having failed their children. Specifically, parents with children in charter schools cite higher academic standards, a reduced overall school census with smaller classes, a more compatible educational philosophy, and better educators as their reasons for selecting a charter over a typical public school (Manno et al., 1998a).

Two basic types of charter schools exist: conversion schools, which were once either traditional public or independent schools (private) before converting to charter status, and new schools, which come into existence as a result of their charter (Manno et al., 1998b). Charter schools serve as public institutions being financed with tax dollars and accountable to public authorities for their performance. In parallel, these hybrid-public schools receive freedoms similar to proprietary independent schools: (a) self-governance, in that they are free to reach their educational objectives however they choose; (b) freedom from many regulatory demands; (c) absolute selection and control of their own curriculum, staffing, budget, and organization; and (d) some choice in which children attend their school.

How are Charter Schools Managed and Organized?

SCHOOL SIZE

By virtue of their freedom to be self-determining, there is no typical model for charter schools. However, some similarities exist across charter schools. In general, charter schools are relatively small. In 1998–1999 the median number of students in charter schools was 137 in comparison with the 475 median for all public schools. Newly opened charter schools tend to be even smaller, their median enrollment being fewer than 100 students per school at their founding. In turn, this contributes to a lower student/educator ratio. In 1998–1999, the student-teacher ratio for charter schools was 16.0 in comparison with 17.2 for public schools (U.S. Department of Education, 2000).

MISSION AND CURRICULUM

By their very nature, charter schools tend to be innovative in their mission, and therefore tend to reflect a diverse curriculum. In many cases, educational programming is inventive and novel, apparently unhampered by adherence to the canons of educational lore. Other charter schools reflect models of existing alternative schools (e.g., Montessori, magnet schools).

EDUCATIONAL LEADERSHIP

The educational leadership and personnel management of charter schools also reflect variety. Individual administrators whose primary motivation is to have an opportunity to achieve excellence and escape the constraints of traditional schools head a majority of charters schools. Some charter schools outsource a significant portion of the managerial duties and responsibilities to third parties, while others have a single person or a large board who manage the school (Manno et al., 1998b).

STAFFING MODELS

Because charter schools in most states are exempt from the state's requirement for licensed educators, charter schools maintain staffing plans unhampered by the demands to hire certified individuals with any formal education in the subject area they teach or the work they perform. In many cases the fact that their teachers are *not* certified or licensed by a state agency is a point of pride. Particularly in chartered religious foundation establishments, it is the individual's acceptance of specific religious tenets that provides them the necessary credibility to teach the general curriculum.

FACILITIES

Facilities vary widely, especially in the case of start-up schools. Some schools have access to an unused school facility while others are forced to opt for storefronts or, in some cases, "schools without walls" (Manno et al., 1998b). This has led to problems with safety, building, and disability-access code violations and related problems associated with the public congregation in marginal facilities.

SCHEDULING

Charter schools have been equally creative in their scheduling practices, largely possible because charter schools are not mandated to be open a minimum or maximum number of hours per day (or even to maintain set hours each day). Many charter schools schedule longer school days and years, some add a weekend school day, and a few are functional 24 hours/7 days a week. "Wraparound" child-supervision (i.e., before and after school child care) is available in almost three-quarters of charter schools as an additional service to employed parents (Manno et al., 1998b; U.S. Department of Education, 2000).

TECHNOLOGY

In conjunction with the innovations in scheduling and facilities, many charter schools have devised unique ways in which to integrate technology more efficiently than have their traditional counterparts (Manno et al., 1998b). In 1998–1999, the estimated mean student-to-computer ratio in charter schools was 8.9 in comparison with the estimated average for all public schools of more than 10.0 (U.S. Department of Education, 2000).

PARENT INVOLVEMENT

Charter schools incorporate many ways to encourage parental involvement, including parent mentors and classes taught either for or by parents (Manno et al., 1998b). Moreover, one of the highest levels of parental satisfaction with charter schools comes from their involvement of parents. More than 60% of parents say that the charter school is better at involving parents than was their child's previous (public) school (Manno et al., 1998a).

FISCAL MANAGEMENT

One of the greatest problems faced by charter schools relates to financial management, budgeting, and ongoing fiscal stability (Manno et al., 1998a). Although 73% of charter schools have primary control of their budget (U.S. Department of Education, 2000), and all are in imminent danger of closing if they are not fiscally sound (Bierlein, 1997), the vast majority of charter schools are administered by people with little or no business expertise (Bierlein, 1997). Furthermore, charter schools receive less per capita funding than do traditional public schools and, unlike their traditional counterparts, are expected to produce results or face closure (Manno et al., 1998a). Thus, in response to these fiscal demands, charter schools have needed to employ creative budgeting and reporting strategies to manage their resources, including partnering with both for-profit and nonprofit companies and outsourcing for professional as well as management services (Manno et al., 1998a).

Who Attends Charter Schools?

Critics of charter schools fear that they will be bastions of elitism admitting only the cream of the crop into their schools (Vanourek, Manno, Finn & Bierlein, 1997a). Investigation, however, shows that this is hardly the case. In the Hudson Institute's study of charter schools, parents reported that their children had behavioral problems (11.5%), learning disabilities (9%), and physical disabilities (2%) at point of entry (Vanourek et al., 1997). Moreover, the children in these charter schools were more likely to be members of an economically fragile or racial minority group than were their counterparts in all public schools (one-half compared with one-third). Furthermore, many of these children came from low-income households; for example, 41% of families in the Hudson Institute's study had annual incomes under $30,000. The U.S. Department of Education's most recent survey of charter schools supports the Hudson Institute's findings. They found that charter schools enrolled a smaller percentage of white students than all public schools (50% compared with 63%), served a slightly higher percentage of students who were eligible for free or reduced price lunches (39% versus 37%), and enrolled only 3% proportionally fewer students with disabilities than did public schools (U.S. Department of Education, 2000).

IS THERE AN UNTAPPED NEED FOR SCHOOL PSYCHOLOGISTS?

While, on the surface, the fact that charter schools enroll fewer students with disabilities may seem evidence that the schools are discriminatory in their admissions. To the contrary say the charter school proponents, who assert that they develop individualized plans for every student thereby avoiding a special education label and its presumed stigma (Vanourek et al., 1997).

In these settings school psychology's problem-solving procedures may be attempted but rarely are codified within a formal individualized educational plan (IEP). Interventions are implemented but not evaluated with the depth or frequency required by recognized IEPs. Furthermore, since many charter schools are founded specifically in order to serve a special population of students at educational risk, it would seem a natural outlet for psychology services to schools. However, there has been a marked reluctance to employ psychologists. This reluctance may stem from a discomfort with the *psychology* element in the professional title. Even in those schools where students are selected on the basis of their acting-out behaviors that may co-exist with emotional disturbance, it is routine to decline the services of a mental health provider in favor of a "behavior management specialist."

BEST PRACTICES FOR SCHOOL PSYCHOLOGY IN CHARTER SCHOOLS

Understanding the Challenge of Autonomy Versus Accountability for Charter Schools

The difficult-to-pinpoint element in any comparative analysis of different forms of service delivery is embedded in answers to the question of, *What comprises success for charter schools?* Success is mentioned repeatedly as a criterion for continuation of a school's charter, and therefore appreciating its significance to charter schools is crucial. Clearly, success means different things to different people. For the purposes of this discussion, success will mean that students acquire the academic and social skills necessary to be viable, independent members of society. This definition still leaves significant components to decipher. Academic success encompasses all school subjects and related material. Social success includes getting along with others, acting responsibly for self and others, being able to function in many different settings, and understanding consequences.

Accountability, in this context, refers to a school's ability to lead their pupils to demonstrate competency in the educational realm and preparedness for transition into the world of work. Public schools are subject to reviews and audits and similar procedures such as proficiency tests to demonstrate that children are learning appropriately. Not only do public schools have to show that their children are learning, but they have to show that the teachers are using any state-mandated curriculum that exists. Charter schools do not have this same measure of accountability, and states vary widely in what measures they expect alternative forms of education to complete.

As was discussed earlier, the basic premise of charter schools is the freedom to realize the goals of the charter by whatever means the school's administration sees fit. In return, charter schools are held to a *higher standard* of accountability for academic results than are traditional public schools. Therefore, if the school fails to meet the goals specified within its charter, the charter-granting agency may close the school by revoking its charter upon review (Hassel & Vergari, 1999). This high-stakes penalty is markedly absent in most summative reviews of traditional public schools. Charter schools must therefore be able to make a persuasive case for the renewal of their charter.

A charter school's ability to prove itself as successful begins at the state legislative level. The best charter laws establish explicit provisions for evaluating a school's effectiveness. According to Manno et al. (1998a, p. 558), these provisions include

1. The school must produce satisfactory academic achievement by its students on state- or district-wide tests and similar measures.

2. The school must demonstrate success in meeting its own goals—academic and other—as set forth in its charter or contract.

3. The school must use public funds responsibly.

4. The school must comply with all applicable laws and regulations (such as public health, building code, due process, and civil rights) that are not waived for charter schools.

In 1996, the American Federation of Teachers found that only 17 of 25 states that then had adopted charter legislation required charter schools to use the same proficiency tests as other state public schools to document student achievement (American Federation of Teachers, 1996). Manno et al. (1998a) conclude that most states are accustomed to rule-compliance rather than an academic-accountability system and that most states are still in the process of developing standards for testing the academic achievement of students enrolled in their *traditional* public schools, let alone in charter schools (Manno, 1997). In essence, most states are simply unprepared to evaluate a school on the basis of academic achievement (Hassel & Vergari, 1999). However, without the use of comparable measures, it is fundamentally impossible to gauge the academic effectiveness of charter schools relative to other schools on a district-, state-, or nation-wide level.

How then can we decide which schools have and which have not lived up to their contract? Without specifying these important details, charter schools may be destined to fail from the outset. Even within states that have comparable mandated standardized tests for all public schools, the problem for many charter schools is not solved. Hassel found that 75% of charter schools utilize the same tests that are used by traditional public schools in their state (Hassel & Vergari, 1999). However, because of the vastly different curricular objectives of charter schools, state standardized tests are highly likely to be inappropriate and ineffective for assessing the academic achievement of charter school students whose curriculum did not reflect the content or information the test evaluated (Hassel & Vergari, 1999; Manno, 1997).

In an attempt to counter inadequate regulations, it is important for charter schools to make written provisions for accountability within their charter application and to have an internal monitoring system in order to ensure the goals are being met. Ideally, Hassel and Vergari (1999) have suggested that schools should detail explicit and measurable academic goals within their charter application. Additionally, schools should develop internal monitoring strategies that track school performance and student performance in order to highlight *early* signs of trouble within the school (Manno, 1997). Both Hassel and Vergari (1999) and Manno (1997) have expressed concern that, because of a general lack of expertise among charter school founders in crafting feasible academic goals, some stipulations may be virtually unobtainable from the outset.

Charter schools employ a range of systems to track student performance. Almost all utilize standardized assessments (96%); 89% use student demonstrations of their work; 81% utilize student portfolios; and performance assessments are used by 74% of charter schools. Again, almost all (94%) use a series of alternative assessments and display progress and accountability through multiple forms of student assessment (U.S. Department of Education, 2000). While most of these non-standardized methods of performance assessment may be more compatible with a charter school's mission and philosophy, such methods usually do not allow for easy comparison with traditional schools' outcomes.

Charter regulations call on schools to agree on accountability plans that show the kinds of progress in student performance that need to be attained for the charter to be renewed. Once the achievement goals are agreed upon, it is then up to the charter teachers to implement a model curriculum for attaining those goals. The major frequent complaint from public school education boosters, and those unsupportive of the charter movement, is that the goals are poorly articulated. As already noted, while some charter schools participate in the same statewide tests that are completed in public schools, others do not. This provides an unsystematic view of students' achievement in charter schools.

The Supporters and the Critics

Those who argue in favor of charter schools point to the presumed benefits of competition, democratic choice, and additional options for parents in the selection of educational settings for their children. They note that charter schools foster innovation and suggest that this reflects significant improvement in the learning environment.

The detractors decline from viewing the relatively few charter settings as either "competition" or as beneficial, saying that their existence is a drain on the public purse that supports traditional neighborhood schools. They also point to a nationwide lack of physical facilities of adequate standard for children's education and attest that virtually every educational innovation or reform evident in charter settings can be readily duplicated within existing public settings. Thus, they say, charter schools are unnecessary. Detractors also cite elitism, inattention to diversity, and neglect of equity issues as points of contention.

Both charter enthusiasts and opponents tend to depict charter schools as evidence of revolutionary change, a policy earthquake, and unprecedented and heretofore unimaginable innovation. Both groups are standing too close to the objects they are describing, suggest the authors of *Charter Schools in Action* (Finn, Vanourek, & Manno, 2000).

What is the Impact on Student Achievement?

Given the roadblocks to comparing charter school students to their peers in traditional public schools, how then are charter school students performing? The quick answer is that it is just too soon to tell. Because charter schools as a whole are so new, it is virtually impossible to know what effect they are having on their students (Hassel & Vergari, 1999; U.S. Department of Education, 2000; Manno et al., 1998a). In addition, Vanourek et al. (1997) warn against judging the academic performance of schools in their early years, since scores may be more of an expression of what the student brought from his or her previous educational experiences rather than a measure of the gains or losses since enrollment.

Although quantitative outcomes may be premature, charter schools are taking some qualitative reporting steps to describe measuring student achievement. For the most part, these performance indices consist of self-report data. The U.S. Department of Education (2000) found that charter schools are using parent and student surveys as indirect approaches to measuring their system-wide progress (83% utilized parent surveys; 71% used student surveys). Manno et al. (1998a) found that satisfaction among parents (another popular indicator of school success) was quite high. Among parents who reported their children were performing poorly at their previous school, 44% believed that their child was doing "excellent" or "above average work" in the charter school. Similarly, children in charter schools believed that they were improving academically. Of those who rated themselves as having achieved "poorly" at their previous schools, 45% felt they were doing excellent or above average work in the charter school (Manno et al., 1998a). Further, 38% of parents with children in special education rated their child's performance as either excellent or above average (only 16% felt their child's performance was excellent or above average in his or her previous school) (Manno et al., 1998a). The lengthy waiting lists for most charter schools serve as an additional, albeit indirect, measure of the public perception of their performance (U.S. Department of Education, 2000; Vanourek et al., 1997).

Some preliminary data regarding established charter schools is available. Vanourek et al. (1997) report that academic gains were larger than typically found in traditional public schools for six of eight Massachusetts charter schools that were tested. Further, in a 1996 pilot administration of the Minnesota basic graduation test, two out of three charter schools had greater percentages of passing scores in Reading and one in two in Mathematics than other schools in the host district (Vanourek et al., 1997).

What is the Impact on Traditional Public Schools?

The charter school phenomenon has many potent implications for *the revitalization of America's traditional public schools* (Manno et al., 1998b). First, since competition promotes change, charter schools have forced their traditional neighborhood schools to engage in self-analysis and enact modifications reflecting continuous quality improvement. Second, charter schools tend to be more consumer-oriented than producer-oriented. That is, charter schools focus upon keeping parents and students satisfied, whereas traditional public schools have tended to be more concerned with employee satisfaction and maintaining the goodwill of "expert judges" such as accreditation bodies, teacher-educators, and national learned societies. The radical growth of charter schools has encouraged traditional neighborhood schools to recognize the power of the customer and involve them as stakeholders and change-agents in their school's day-to-day management.

CHOICE

In addition, charter schools have widened educational choice for all families. Unlike most traditional public schools, charter schools realize that the needs of families, even low-income families, demonstrably differ. Thus, charter schools represent an economic alternative for any family whose child is not thriving in a traditional public school. Charter schools' freedom to be flexible leaves many of them more prepared to adapt to changes that occur in their student body, families, and communities than is true for their public counterparts (Manno et al., 1998b; North Central Regional Educational Laboratory, 2000).

CLIMATE

Another possible insight for public school personnel, particularly school psychologists interested in promoting school safety, is the intimate climate that most charter schools manage to create. Even the largest of the charter schools are organized specifically to encourage regular and direct contact among stakeholders. Since charter schools are voluntary, everyone at the charter school, from the students and their families to the educators and administrators, wants to be there. In turn, this enables charter schools to build stronger school communities. It may also be that the

474

sense of community fostered within the relatively small charter schools further enhances their school community's safety.

ACCOUNTABILITY

One of the most critical implications for traditional public schools is embedded in the concept of *accountability*. Charter schools are accountable for their results and face serious consequences if targets are not met. This is not the case for the majority of traditional public schools where continued financing is never at risk even in the face of deplorable academic outcomes. In a real sense, charter schools may be subject to the greatest consequence of all for failure; that is, charter schools are voluntary and therefore students and staff may leave and, in the end, the school may lose its charter and be forced to close if the results specified within its charter are not produced. However, this penalty has very rarely been enacted. Since 1991 there have only been four schools closed for failure to meet their charter (although many have voluntarily closed their doors for unknown reasons). Nonetheless, as Ravitch and Viteritti (1997) suggest, "the very existence of such schools will cause educators within the existing system to demand clearer standards by which to measure school performance" (p. 14).

STAFF

Finally, charter schools, unlike traditional public schools, have liberty in the area of staff selection. As was discussed earlier, charter schools are not limited to hiring only certified or licensed teachers and support personnel. In addition, charter schools are free to make their own decisions about workloads and compensation. Such issues have important implications for educators in traditional public schools and for their negotiating units nationwide.

What is the Responsibility of Charter Schools to Students With Disabilities?

Special education is the domain in which charter schools are most required to function like traditional public schools (Vanourek et al., 1997). As public schools, charter schools are required to comply with the Individuals with Disabilities Education Act (IDEA), Section 504 of the Rehabilitation Act of 1973 and Title II of the Americans with Disabilities Act of 1990 (Ahearn, 1999; U.S. Department of Education, 1998, 2000). Thus, it is imperative for charter schools to address responsibly the special education needs of their students (Manno, Vanourek, & Finn, 1999) while at the same time keeping in mind that no school, charter or otherwise, can accommodate every need of every disabled child.

It is important for charter schools to ensure that students are not denied admission on the basis of a disability and that they provide both due process and the appropriate staff to execute each students' IEP (U.S. Department of Education, 1998; Manno et al., 1999).

Specifically, the IDEA Amendments of 1997 refer to charter schools in three sections:

1. Section 611 (f):(4)(A): Authorizes grants to be made to a state, "In any fiscal year in which the percentage increase of the state allocation under this section exceeds the rate of inflation" (Ahearn, 1999). The state, in turn, shall make sub-grants to local education agencies to "assist them in providing direct services and in making systemic change to improve results for children with disabilities" (Ahearn, 1999). *The section specifies that sub-grants may be allocated to charter schools.*

2. Section 612 (a):(21): Establishes directions for state eligibility for financial assistance, and requires the creation of a state advisory panel in order to "provide policy guidance with respect to special education and related services for children with disabilities in the state" (Ahearn, 1999). The section specifies that membership of the panel shall include *representatives from charter schools*.

3. Section 613(a):(5): Provides conditions under which charter schools are eligible for financial assistance (Vanourek et al., 1997). The Local Educational Authority (LEA) *must serve children with disabilities* in the "same manner as it serves children with disabilities in its other schools" (Ahearn, 1999). And *provide funds* to those schools in "the same manner as it provides those funds to its other schools "(Ahearn, 1999).

These IDEA Amendments, require that: (a) when charter schools are public schools of the LEA, the LEA must serve children with disabilities in those schools in the same manner that it serves children with disabilities in its other schools and provide Part B funds to those school in the same manner that it does to the other schools and (b) a state education agency may not require a charter school that is an independent LEA to jointly establish its eligibility with another LEA (e.g., local traditional school district), unless it is explicitly permitted to do so under the state's charter school statue.

State laws regarding charter schools vary immensely. However, most state charter school regulations contain few specific references to students with disabilities (Ahearn, 1999). The only reference that most states make to special education in charter schools is in an information packet that guides potential school developers and entrepreneurs (Ahearn, 1999).

Unfortunately, at both the state and federal levels, the rules by which charter schools must operate in order to access funding are often fundamentally inappropriate given the nature and mission of charter schools (Vanourek et al., 1997; Manno et al., 1998a; Ahearn, 1999). Typically, the state statutes that establish charter schools are in conflict with the preexisting legal requirements (Ahearn, 1999). Charter schools, many of which are established to serve special students in non-standard ways, do not fit easily within the relatively bureaucratic structure of IDEA and Section 504 (Vanourek et al., 1997; Manno et al., 1998a).

While 95% of charter schools report offering special education services (U.S. Department of Education, 2000), as a whole charter schools still enroll 3% fewer disabled students than do public schools (8% versus 11%, respectively) (U.S. Department of Education, 2000). However, in a contrary interpretation, Vanourek et al. (1997) suggest that charter schools may actually enroll a greater proportion of disabled students (12.6%). The reason for this discrepancy is said to be due to the chronic underreporting of disabled students by charter schools (Vanourek et al., 1997).

In order to understand this last point, it is necessary to have a background regarding the allocation of special education funds to charter schools. First, under IDEA, the Department of Education allocates funds annually to states on the basis of the reported number of students receiving special education and related services for the previous fiscal year. In turn, states use their own formulas to distribute these funds (*Charter schools: Issues affecting access to federal funds.* (September 16, 1997). Hearings before the Subcommittee on Early Childhood, Youth, and Families, Committee on Education and the Workforce, U.S. House of Representatives. Testimony of Cornelia M. Blanchette (GAO/T-HEHS-97-216)). Specifically, IDEA funds and services are allocated to charter schools on the basis of whether the school is treated as an *independent* LEA or is viewed as a *dependent* of an LEA . Charter schools that are independent LEAs may apply directly to the state for IDEA funds, and states are required to include charter schools that are eligible independent LEAs in their block grant distribution of federal funds (Ahearn, 1999). In turn, independent charter schools must meet all federal and state eligibility requirements as any other local district (Ahearn, 1999). These funds are significantly greater, but have more strings attached, than are the funds for charter schools engaged in providing special education services which are dependents of an LEA. Dependent charters receive a proportional, per capita share of the federal funds received to serve children with disabilities *based only on the federal flow-through funds and not on locally generated tax bases.* Because of relatively burdensome eligibility qualification requirements that are time consuming to complete, some charter schools that could receive funds as independent LEAs do not apply for and thus do not receive these funds and remain as dependents of an LEA.

Another reason for underreporting and underaccess to federal funds is that many charter school administrators are wholly unfamiliar with the special education funding process. Many do not even realize that they are eligible for IDEA funds (*Charter schools: Issues affecting access to federal funds.* (September 16, 1997). Hearings before the Subcommittee on Early Childhood, Youth, and Families, Committee on Education and the Workforce, U.S. House of Representatives. Testimony of Cornelia M. Blanchette (GAO/T-HEHS-97-216). When they do realize their eligibility, many charter schools are incapable of receiving IDEA funds because they do not know the number of newly enrolled students who had an IEP in the prior school (U. S. Department of Education, 1998). Additionally, the time invested in applying for, complying with, and monitoring the reporting requirements of IDEA funds is often a daunting task for a charter school's small and typically inexperienced administrative staff. Finally, even when a charter school receives IDEA funds, they may not be able to be certain that they have received the appropriate level of funding because of charter school personnel's lack of familiarity with state funding formulas and granting procedures.

There are several additional barriers to a charter school's access to federal IDEA funds (U.S. Department of Education, 1998). First, many charter schools cite a philosophical difference with the use of a special education/disability label (Fiore, Warren, & Cashman, 1998; U.S. Department of Education, 1998; *Charter schools: Issues affecting access to federal funds* (September 16, 1997)). Hearings before the Subcommittee on Early Childhood, Youth, and Families, Committee on Education and the Workforce, U.S. House of Representatives. Testimony of Cornelia M. Blanchette (GAO/T-HEHS-97-216). Often, charter schools are created specifically in order to serve an educationally at-risk population. Since most charter schools attempt the creation of unique learning plans for all students, they reject the idea of "tracks" or "IEPs" for students with special needs (Vanourek et al., 1997). To further clarify, the administrators of charter schools often feel that they deliver individualized instruction to *all* students and are reluctant to report students as recipients of special educational services. Finally, many parents of special education services select charter schools specifically to avoid what they perceive as special education labeling and stigmatizing tracking.

Because charter schools often either specifically target a special population or are seen as refuges for them, charter schools may very well end up attracting a greater proportion of special needs students into their ranks (Vanourek et al., 1997). As Mcaughlin and Henderson (1998) note, "for many parents, the charter schools were becoming 'schools of last resort'" (p. 105). Because many charter schools specialize in the education of special populations, they may actually generate a greater obligation to serve children with disabilities, especially where they operate as an independent LEA (U. S. Department of Education, 1998; Ahearn, 1999).

Finally, although data reflecting rigor are currently unavailable, it is possible to discern at least a *perceived positive impact* of charter school education upon children in special education, based on parent satisfaction surveys. Manno et al. (1999) report that among parents of special needs children in charter schools, two out of three stated that they believed that the charter school's curricula and teaching were superior to that at the school their child would otherwise attend. Furthermore, while only 16.5% of parents rated their special education child's academic performance at their previous school as above average or excellent, more than double that amount (37.8%) felt that their special education child was performing above average or excellently within the charter school (Vanourek et al., 1997). The reasons for this perception of higher-quality outcomes from charter schools, compared with their traditional counterparts, is difficult to fathom if one begins with a presumption of the superiority of the public education service model. However, for parents who have no such standard against which to measure their children's success, there is a fairly clear statement of preference evident. The reason for this discrepancy would be a useful beginning point for a school psychologist researcher wanting to understand the intangibles that garner strong support for the charter movement from among the parent group.

SUMMARY

This chapter has outlined the motives for the development of charter schools, the rationales expressed by their protagonists and antagonists, and the characteristics of size, educational leadership, staffing patterns, curriculum variability, facilities, scheduling, approaches to technology and fiscal management, and parental involvement.

To date, there has been almost no significant interaction between the field of school psychology and the charter school movement, except in isolated pockets. Best practices for school psychologists in charter schools still remain a vision, as yet largely unarticulated into practice. Where school psychologists are already functioning as part of a charter school's team they typically are contracted to meet, minimally, the requirements of federal regulations protecting the rights of children with disabilities.

With anticipated continuing rapid growth of charter movement it is timely for school psychologists to articulate a more appropriate role for their professional services. In the service of children in contemporary charter establishments the role possibilities are wide open. The greatest *current need* is not special education consultation or mental health services. Rather it is in the design and implementation of accountability measuring systems, for these are a prerequisite for the schools' continuation. Thus, the opening gambit for school psychologists attempting entry into this exciting field may be through their skills in the objective appraisal of system data: as a program evaluation specialist.

There are few limitations on the breadth of role that a school psychologist might fill, a signal strength of the charter movement. However, there are demonstrable limitations to the development of *professional* school psychological services in terms of tenure, compensation levels, and similar proprietary contractual terms when compared with employment in comparable public school settings.

This national report contains information from 27 of 37 states (plus Washington, D.C.) having charter school regulations. The study's focus is on charter schools' organizational characteristics, student characteristics, implementation strategies, student achievement patterns, and their overall impact on public education. Includes a discussion of accountability and assessment, and implementation challenges faced by charter schools.

II.

Improving Student Performance

33 Best Practices in Designing, Implementing, and Evaluating Quality Interventions

Kristi R. F. Upah
W. David Tilly III
Heartland Area Education Agency 11

OVERVIEW

In recent years, the trend in school psychology service delivery has shifted toward a problem solving focus; that is, an approach to developing interventions and ensuring student outcomes rather than determining failure or deviance (Deno, 1995; Reschly & Ysseldyke, 1995). This direction is reflected in major National Association of School Psychologists (NASP) publications, such as the previous edition of *Best Practices* (Thomas & Grimes, 1995) and *Blueprint II* (Ysseldyke et al, 1997) as well as other major professional publications (e.g., Rathvon, 1999; Reschly, Tilly, & Grimes, 2000; Shinn, Stoner, & Walker, in press). With this shift in practice comes the challenge and responsibility for school psychologists to ensure they are designing, implementing, and evaluating *quality* interventions. This chapter will assist practitioners by presenting critical quality indicators of interventions. Space limitations preclude a comprehensive treatment of each intervention component. Many of the quality indicators could and do have complete chapters or books written on them elsewhere. Hence, this chapter will provide a brief discussion of each component, along with references to more complete sources of each indicator. In addition, innovation configurations will be presented for school psychology practitioners to monitor their implementation of each component that will allow them to assess their own progress in designing, implementing, and evaluating quality interventions.

BASIC CONSIDERATIONS

Effective interventions are an essential feature of alternative service delivery systems and educational reform in an effort to meet the needs of all students (Graden, Zins, & Curtis, 1988; Stoner, Shinn, & Walker, 1991). In the previous edition, Tilly and Flugum (1995) defined "intervention" as *a planned modification of the environment made for the purpose of altering behavior in a pre-specified way.* Emphasis was placed on three components of this definition: (a) *planful*, the procedures to be applied are specified clearly and completely; (b) *environmentally focused*, the actions taken modify the environment and not the individual; and (c) *goal directed*, the behavior is altered in a pre-specified way. For the purposes of this chapter, let us expand upon the previous definition by viewing an intervention as *a set of procedures and strategies designed to improve student performance with the intent of reducing the student's problem.* Note that neither definition refers to a location for implementation or a specific person who will be implementing the intervention. Both definitions suggest that interventions can, and should, be implemented in any setting where they are needed (e.g., general education or special education setting, home or school) and implemented by whomever the appropriate person(s) may be (e.g., general education teacher, special education teacher, school psychologist, parent, support staff).

Quality indices of interventions have been described in the behavioral literature for over 25 years (i.e., Baer, Wolf, & Risley, 1968; Bijou, 1970). Since then many others (e.g., Ikeda, Tilly, Stumme, Volmer, & Allison, 1996; Macmann et al., 1996; Reynolds, Gutkin, Elliot & Witt, 1984; Schendel & Ulman, 1989) have identified components of interventions or models of problem solving that reflect quality indices. Although there are various models in practice, they all address (to varying levels of specificity) the major problem-solving stages seen in Bergan and Kratochwill's (1990) behavioral consultation model: problem identification, problem analysis, plan implementation, and problem evaluation. Rathvon (1999) used these same four stages in her intervention assistance process.

In the last edition of *Best Practices*, Tilly and Flugum (1995) proposed a finer-grained nine-component model as a best practice standard for the development and documentation of interventions. In addition to the six quality indicators presented by Flugum and Reschly (1994)—(a) a behavioral definition of the target behavior; (b) a direct measure of the student's behavior in the natural setting prior to intervention implementation (baseline data); (c) a step-by-step, or systematic, intervention plan; (d) implementation of the intervention as planned (treatment integrity); (e) graphing of intervention results; and (f) direct comparison of the student's post-intervention performance to baseline data—four other problem-solving components were identified: (g) systematic problem validation, (h) functional analysis of the problem, (i) goal setting, and (j) systematic formative evaluation of program effects (this step was combined with Flugum and Reschly's "direct comparison of post-intervention performance to baseline" to become "formative and summative evaluation"). Upah (1998) examined the validity of the best practices in intervention design and implementation presented by Tilly and Flugum by using objective, permanent product indices of intervention quality. This study found when practitioners' interventions contained these nine components with a high level of quality, it was more likely the intervention(s) led to positive student outcomes.

Upah's (1998) research, however, found that some of the components could be broken down further owing to the complexity of the indicator. This further separation, while creating additional components, allows for further clarity and isolation of specific indicators that may have been overlooked in past research and practice. As a result, a 12-component quality indicator model is presented as a best practice standard for designing, implementing, and evaluating quality interventions. These quality indices include:

1. Behavioral definition
2. Baseline data
3. Problem validation
4. Problem analysis steps
5. Goal setting
6. Intervention plan development
7. Measurement strategy
8. Decision-making plan
9. Progress monitoring
10. Formative evaluation
11. Treatment integrity
12. Summative evaluation

The 12 quality indicators will be presented within the four stages of behavioral consultation (Bergan & Kratochwill, 1990) since many problem-solving models follow these stages: problem identification, problem analysis, plan implementation, and problem evaluation. Table 1 illustrates how the four stages of problem solving are related to each of the 12 quality indicators. A flowchart depicting the 12 intervention components and their relationship is contained in Figure 1.

BEST PRACTICES

Problem Identification

The first step in the problem-solving process is to identify and define the problem. A *problem* is defined as *the difference between what is expected and the actual student behavior or performance*. This definition helps to further clarify the intent of problem solving; that is, to create an effective solution to bridge, and ultimately close, the gap between the student's performance and the expected behavior. The activities at the problem identification stage are intended to describe, validate, and determine the magnitude of the problem. The school psychologist and other members of the problem-solving team must answer three major questions during problem identification:

Table 1. Quality indicators addressed within the problem-solving process

Problem solving stages	*Intervention Components*
Problem identification	• Behavioral definition • Baseline data • Problem validation
Problem analysis	• Problem analysis steps
Plan implementation	• Goal setting • Intervention plan development • Measurement strategy • Decision-making plan
Program evaluation	• Progress monitoring • Formative evaluation • Treatment integrity • Summative evaluation

1. What is the behavior of concern and/or the desired behavior? (behavioral definition)

2. What is the student's current level of performance in the target behavior? (baseline data)

3. How does the student's behavior compare to peers' behavior or environmental expectations? (problem validation)

BEHAVIORAL DEFINITION

Behaviors that are the subject of interventions must be described in specific, observable, and measurable terms (Alberto & Troutman, 1986; Howell & Nolet, 2000). This process is called operationally defining a behavior. The importance of a behavioral definition has been emphasized for nearly three decades (e.g., Baer et al., 1968; Bijou, 1970). Twenty years later, Baer, Wolf, and Risley (1987) continued to support defining the behavior in observable, quantifiable terms. Other authors (e.g., Deno, 1995; Grimes, 1981; Reynolds et al., 1984; Steege & Wacker, 1995) have recognized how essential an accurate behavioral definition is to the success of the intervention. A behavioral definition of the problem ensures that the school psychologist and other involved persons share a common understanding of when the behavior is or is not occurring. As a result, operational definitions of student behavior allow for a reliable measurement of outcomes (Kazdin, 1982; Steege & Wacker, 1995).

An operational definition must meet three criteria: (a) *objective*, the definition should refer to observable characteristics of behavior describing the actions that can be seen or heard; (b) *clear*, the definition should be so unambiguous that it could pass the "stranger test" (it could be read, repeated, and paraphrased by observers); and (c) *complete*, the definition should delineate both examples and non-examples of the behavior so that differences between occurrences and non-occurrences of the behavior can be discerned (Hawkins & Dobes, 1977; Howell & Nolet, 2000; Kazdin, 1982; Tilly, Reschly, & Grimes, 2000). To write behavioral definitions meeting these criteria, it may be helpful to use a standard format. One format that is particularly useful is:

> *Target behavior* means that *target student* (*action verbs*). Examples of *target behavior* include (1)..., (2)..., (3).... Non-examples of *target behavior* include (1)..., (2)..., (3)....

This format requires that attention is directed at what a student actually does when performing the behavior, providing a vehicle for efficient writing of definitions.

BASELINE DATA

Measurement of the target behavior in the natural setting prior to plan implementation is essential to interventions (Casey, Skiba, & Algozzine, 1988). The establishment of the student's current level of functioning provides a baseline that is useful in evaluating the existence of the problem behavior, the effectiveness of the intervention, and the degree of student progress (Reynolds et al., 1984; Schendel & Ulman, 1989; Sulzer-Azaroff & Mayer, 1991). The baseline

Yes
Program for Maintenance and Generalization

data component involves three steps: (a) establishing the relevant dimension(s) of the problem behavior, (b) developing a method to systematically measure the behavior, and (c) collecting data on the behavior prior to implementing an intervention.

When identifying the appropriate dimensions of the target behavior, FLITAD is a useful acronym to remember. The letters in FLITAD reflect the first letters of the possible dimensions of the behavior that may be problematic (Sulzer-Azaroff & Mayer, 1991): *F*requency, the number of times a behavior occurs; *L*atency, the elapsed time from the presentation of a stimulus and the response or behavior; *I*ntensity, the strength or force with which a behavior is expressed; *T*opography, the configuration, form, or shape of a response or behavior; *A*ccuracy, the extent to which the behavior meets standards or is correct; and *D*uration, the length of time that passes from onset to offset of a behavior.

Behavioral measurement strategies often are selected based on the dimension of behavior that is problematic. Behaviors that manifest as frequencies are best tallied. Behaviors of latency and duration are best measured by using time in seconds or minutes. Intensity can be scaled on a rubric, but is best measured by using objective scales such as decibel meters or pounds of pressure per square inch. Accuracy is measured through scoring of permanent products or probes.

A measurement strategy is used to develop the method of systematically measuring behavior. The following questions should be answered when developing a measurement strategy: (a) *How will the data be collected?* (b) *What materials will be used to collect data?* (c) *In which setting(s) will data be collected?* (d) *Who will be responsible for collecting the data?* (e) *When (and how often) will the data be collected?* In designing the measurement strategy, there are three important points to consider. First, the behavior must be measured directly in the setting where it is perceived to be problematic. Second, the measurement strategy used to collect information should be accurate, objective, and related directly to the relevant dimension of the behavior. Third, this same strategy will be used throughout the intervention to monitor and evaluate its effectiveness at improving student performance. As a result, the feasibility of collecting data frequently and repeatedly over time is an issue.

Baseline data collection should consist of repeated measures of the target behavior over several sessions, days, or even weeks until a stable range of behavior has been identified (e.g., no new highs or lows for three data points in a row (Sulzer-Azaroff & Mayer, 1991)). Collection of baseline data serves several purposes related to other intervention components. Documenting pre-treatment levels of behavior provides needed information for validating the problem (problem validation) and later evaluating the program (formative evaluation and summative evaluation). Current performance provides data for predicting future performance in the absence of intervention, thus setting standards for goals and evaluation (goal setting, formative evaluation, and summative evaluation). An opportunity to observe relationships between the problem behavior and other environmental variables provides critical information useful during functional analysis and intervention design (problem analysis and intervention plan development).

PROBLEM VALIDATION

As was stated earlier, a practical method in defining a problem is to conceptualize problems as the difference between what is expected in an environment and what actually occurs (Deno, 1995; Tilly & Flugum, 1995). Problem validation is the process of determining the magnitude of the problem by summarizing the discrepancy between a student's current level of performance and the environmental expectations (Howell & Nolet, 2000). Validating the existence of this discrepancy ensures that a successful intervention will result in a socially meaningful outcome.

In practice, a discrepancy is determined by comparing a student's current level of performance, documented using baseline data, to a standard. The standard must be appropriate to the behavior and represent an acceptable performance level. A useful standard for both academic and non-academic behaviors is peer performance obtained by measuring typical peers' performance on the behavior of concern to find a range of typical performance. If direct peer comparison data are not available, then other local standards might include local building or district norms, teacher/classroom expectations, criteria for the next environment, or school policy standards. Other standards not directly derived from the student's local district might include instructional placement standards, state or national norms, developmental standards, or medical standards. Although these standards provide a less precise comparison standard, they are used primarily when local standards are inappropriate or unavailable.

The school psychologist should ask the problem-solving team two questions when validating a problem (Schendel & Ulman, 1989; Tilly & Flugum, 1995). First, is there a discrepancy between the target student's performance and the performance standard? Second, if a discrepancy exists, then is it large enough to warrant intervention? If the answer to either of these questions is *no*, then the existence of or severity of the problem should be questioned and possibly re-examined. If the answer to both of these questions is *yes*, then the problem is validated and further assessment for the purpose of developing and evaluating interventions is needed.

Problem Analysis

As was mentioned above, the next step is to conduct further assessment for the purpose of designing, implementing, and evaluating interventions. This further assessment determines what is known about the problem and what important and relevant information still needs to be obtained in order to evaluate the underlying causes of *why* the problem is occurring. Problem analysis is a critical step in the problem solving process; that is, problem analysis provides the critical link between the assessment information and intervention procedures. This step is perhaps the most complex and most critical to the selection of appropriate interventions. Indeed, when an accurate problem analysis has been completed, the design of potentially effective interventions becomes less difficult. The major question to be answer by the school psychologist and other problem-solving team members during problem analysis is, *Why is the problem occurring?*

PROBLEM ANALYSIS STEPS

Problem analysis information should be the result of a very specific, question-driven assessment process. There are five steps to problem analysis: (a) identify relevant known information, (b) identify relevant unknown information, (c) generate a hypothesis or prediction, (d) validate the hypothesis or prediction, and (e) link the assessment information to intervention design.

The first two steps involve collecting data in the four domains of instruction, curriculum, environment, and the learner (ICEL). First, all relevant known information pertaining to the multiple domains (i.e., ICEL) of the problem are gathered through record reviews and interviews. Once all relevant known information is considered, information that is relevant to the problem but is unknown needs to be gathered through observations and tests. As information is collected that answers the unknown relevant information this becomes known information from the standpoint of informing future decisions.

After the initial assessments are completed, the third step of problem analysis is hypothesis or prediction statement generation. This process involves making informed statements about why the problem occurs. The typical format for the hypothesis is "*(the problem) occurs because* ______________________." The following format for a hypothesis statement may be more helpful when completing a functional behavioral assessment ~~of a~~ challenging behavior: *The problem is occurring because when (the trigger occurs), the student (behavior) in order to/because (hypothesized function or reason)*. The hypothesis is based on the relevant and alterable information initially generated in the first two steps and leads to a prediction statement. A prediction statement creates the direct and logical link between assessment information and intervention action. The prediction makes a proposition, based on the hypothesis, of what would occur if some other set of factors were in place. The typical format is "*if (a specific action) occurred, then (the problem) would be either increased or decreased*." Predictions are directly related to the original hypothesis and should be composed of specific actions that are reasonable and do-able in the known context of where the problem exists. This process of hypothesis generation and prediction is data driven and focused on refining the problem. As such, this process is very different from simply brainstorming any possible reason for the concern(s). As a result, the hypothesis and prediction statement offer logical explanations for the problem behavior and guide the development of the intervention plan.

The fourth step of problem analysis involves validating the hypothesis and prediction statement. Validation can occur either through implementation of the ultimate intervention or through systematic manipulation of the environment (as stated in the prediction) and observing the effect on student performance. In either case, data are collected through observations or tests to verify or confirm the hypothesis and prediction statement.

Once hypotheses and predictions are validated, the focus of problem solving turns to intervention design and implementation. This final step is the crux of the problem analysis phase of problem solving and is where the accurate matching of known features of identified problems is directly applied in the consideration of the most meaningful and potentially effective interventions. This process is what makes the difference between simply knowing where to find possible interventions and how to accurately apply them in situations where they have the highest likelihood of being successful based on the individual analysis of the student's concern(s). The school psychologist must always keep in mind the skills of the intervention implementers, the reasonability of the intervention selected, and the monitoring requirements of the intervention.

Two specific methods of problem analysis for which school psychology practitioners may wish to learn more about include:

1. Functional Behavioral Assessment (FBA), the process of coming to an understanding of why a student engages in challenging behavior and how student behavior related to the environment through the identification of the antecedents, consequences, and the function served from the student's behavior (Knoster & McCurdy, this volume; Tilly et al., 1998).
2. Curriculum-Based Evaluation (CBE), a systematic decision-making framework for examining the assumed causes of problem behaviors linking assessment to instruction (Howell, Kurns, & Antil, this volume; Howell & Nolet, 2000).

Plan Implementation

At this phase of problem solving, the focus turns to developing and carrying out an intervention plan to resolve the problem. The intervention components addressed at this stage must be logically and empirically related to the identified problem and to the reasons that the problem situation exists. In other words, the actions taken during the plan implementation stage must be based on the specific information derived from the problem identification and problem analysis stages. The school psychologist and other members of the problem-solving team must answer four major questions during the plan implementation stage.

1. What is our desired outcome of the intervention? (goal setting)
2. What are we going to do to achieve that outcome? (intervention plan development)
3. How are we going to know if the plan is working? (measurement strategy)
4. What do we do if the plan works or does not work? (decision-making plan)

GOAL SETTING

The goal is the intended outcome of the intervention; that is, the direction or extent to which the target behavior is to be changed. In the absence of a clearly articulated goal, the effectiveness of the intervention can become obscured. In other words, if we do not know where we are going, then we will not know when we get there. Clearly written, justifiable goals and procedures for evaluating goal attainment are key factors to successful programs (Cobb, 1995; Fuchs, 1995). There are three critical purposes for developing goals: (a) the teaching and intervention are directed, (b) the plan is focused on student outcomes, and (c) the methods for assessment and evaluation are structured (Fuchs, 1995).

Goal statements are based on the problem behavior(s) and should state clearly, in a measurable way, what the student's performance will look like if the intervention is successful. Every goal must be written in observable, measurable terms and include four components: time frame, condition, behavior, and criteria. The *time frame* is when the expected progress is to be accomplished. The *condition* is the specific circumstances under which the behavior is to occur, typically taken from the information obtained during the problem identification and problem analysis stages. The *behavior* is the specific behavioral description of the task to be performed; that is, it may be the target behavior as defined during the problem identification stage or an incompatible behavior that is to replace the behavior of concern. The *criteria* is the standard of how well (e.g., how much, how often, to what degree or level) the behavior is to be performed. The criterion is related to both the student's current level of performance (baseline) and the expected level of performance (standard). However, for some goals the criterion may not be the actual standard used during problem validation in the problem identification stage. Several factors should be considered in setting the criterion: (a) the student's current skill level, (b) the skill/behavior targeted for intervention, (c) realistic growth rates, (d) reporting and follow-up schedules, and (e) the time period covered by your goal.

In most circumstances, a goal statement can both be stated narratively and be represented graphically on a performance chart. For the narrative statement, it may be helpful to use a standard format. A format often used for stating goals is:

> *In (number) weeks, when (condition) occurs, (learner) will (behavior) (to a) (criterion).*

For the graphic display of the goal, the following procedures should be used: (a) choose the central point for the baseline data, (b) draw a vertical line after the baseline data, (c) set a second endpoint at the highest performance level on the date by which you want the student to achieve the goal, and (d) draw a straight line between the two endpoints.

INTERVENTION PLAN DEVELOPMENT

The intervention plan answers questions relevant to solving the identified problem, including who will do what, when they will do it, where the plan will be implemented, how the steps will be completed, and with whom the plan will be implemented (Macmann et al., 1996; Tilly & Flugum, 1995; Howell & Nolet, 2000). This plan ensures the school psychologist and all other parties involved with the intervention share the same understanding of the procedures that will be used, as well as serves as a guide for implementors of interventions and a record of the intervention. Just as an operational definition completely describes a behavior of concern, an intervention plan clearly describes the procedures to be used during an intervention. Applying the "stranger test" to the plan assists in meeting this purpose: The plan should be clear enough that another school psychologist or educator could replicate the intervention and produce the same results (Baer et al., 1968). The clarity of the plan also will facilitate the intervention being implemented as intended, increasing the integrity of the intervention (Fuchs & Fuchs, 1989; see treatment integrity section). Generic descriptions of an intervention (e.g., "social skills training," "differential reinforcement of other behavior (DRO)") are not adequate for intervention plans (Telzrow, 1995).

MEASUREMENT STRATEGY

The major components of the measurement strategy were already developed to collect the baseline data. Modifications may be made to this strategy in relation to where the data will be collected, who will collect the data, and when the data will be collected. However, the overall method and materials used to collect the data should remain the same, allowing accurate comparisons to be made between the student's baseline level of performance and the progress monitoring data. To ensure the integrity of the measurement strategy, what is written in the plan should answer the following questions:

1. How will the data be collected?

2. What materials will be used to collect data?

3. In which setting(s) will data be collected?

4. Who will be responsible for collecting the data?

5. When (and how often) will the data be collected?

DECISION-MAKING PLAN

The final component of plan implementation is to determine how decisions will be made through describing the strategies that will be used for data collection, summarization, and evaluation (Ross, 1995). Tilly and Flugum (1995) identified four specific issues to be addressed: (a) frequency of data collection, (b) what strategies will be used to summarize data for evaluation, (c) how many data points or how much time should occur before data will be analyzed, and (d) a decision rule (guidelines that tell what to do when certain patterns of data occur (Howell & Nolet, 2000)). A number of principles underlie data-based decision making, many of which are derived from single-case research design. Extensive discussion of these issues can be found in Kazdin (1982).

Problem Evaluation

The problem evaluation stage of the problem-solving process focuses on determining how well the intervention plan is working in addition to if and how the plan needs to be changed. During problem evaluation, the school psychologist and other problem-solving team members must answer three major questions:

1. Is the intervention working? (progress monitoring and formative evaluation)
2. Is the intervention being implemented as planned? (treatment integrity)
3. Did the intervention work? (summative evaluation)

PROGRESS MONITORING

Progress monitoring is a primary ingredient in a problem-solving approach (Marston & Tindal, 1995; Shinn, 1989). Throughout intervention implementation, student performance should be assessed so continuous evaluation can occur and interventions may be modified as needed. Carter and Sugai (1989) suggested that the most reliable way to evaluate an intervention is through frequent and repeated monitoring (e.g., one to three times per week) of the target behavior. Data are collected across time on the behavior that was identified during problem identification. These data can be used to create a graphic display for the purpose of illustrating trends in student performance by repeatedly plotting the problematic dimension (i.e., FLITAD) of student behaviors over time. Graphing the student's performance enables the school psychologist and other intervenors to detect slight changes in behavior that otherwise might not be recognized (Casey et al., 1988).

There are many ways to gather progress monitoring data. One well-known method for monitoring basic academic skills progress in reading, writing, or math is the use of Curriculum-Based Measurement (CBM; Shinn, 1989, this volume). Other possible methods include but are not limited to checklists, frequency count, observation procedures, percentages, permanent products, portfolios, rating scales, rubrics, and time (duration or latency). Recall, however, that progress monitoring must use the same procedures that were used to collect the baseline data during the problem identification stage. Consistency in measurement across time allows the school psychologist and other evaluators to be sure that changes in the data result from changes in student performance rather than changes in measurement procedures.

It is important to gather data because it is possible to be fooled about program effects. Without proper data, it is possible to believe that an intervention is assisting the student to achieve some goal when in fact it is not. It is also possible that the student is actually progressing toward some objective, but without the help of data it is believed otherwise (Lovitt, 1991). Simply collecting the data for the sake of collecting data, however, is not enough. It needs to be used in the decision-making process (Tawney & Gast, 1984). Unfortunately, people collect data on the existence of a problem and then monitor progress toward goals, but they may not use the data to make timely changes in unsuccessful interventions (Deno, 1995).

Visual representation of performance using graphs is one means for summarizing and evaluating the data. Graphs are useful for at least three purposes. First, they provide a means of visually summarizing information about student performance, for example current levels of performance, projected performance (a performance goal), and actual performance as it changes over the course of intervention. Second, graphing of results during monitoring may have an important impact on inferences made about the intervention effectiveness and student progress (Skiba, Deno, Marston, & Casey, 1989). For example, "When parents, teachers, and other agents can see visual evidence (i.e., a graph) that a procedure is bringing about the desired change, they are likely to find the evidence reinforcing. Such reinforcement helps to maintain the participation of those people in the treatment program, which is critical if objectives are to be achieved." (Sulzer-Azaroff & Mayer, 1991, p.128). Third, graphing of student performance provides a measure of professional accountability demonstrating how behavior change is functionally related to the intervention being implemented. For clarity of communication, a standard format should be used for graphs (e.g., Parsonson & Baer, 1978; Sulzer-Azaroff & Mayer, 1991).

1. The title should provide a concise description of the nature and purpose of the intervention.

2. Scale captions should establish the identity and meaning of the behavior and measurement procedure.

3. The X-axis and Y-axis scales and their scale units should represent the appropriate type and range of what is measured.

4. Different intervention phases should be labeled on the graph.

5. All relevant data should be shown in an appropriate form

6. A goal line should be present.

When a standard format is followed, additional advantages are to be gained through the use of graphs: (a) They provide a visual that yields quick conclusions and hypotheses; (b) they are quick and easy to make; (c) they can be presented in a wide range of formats with a variety of data types; (d) the messages are immediate, enduring, and accessible to students; (e) there is minimal transfer of data; and (f) the theoretical premises underlying graphs are minimal and well known (Parsonson & Baer, 1992).

FORMATIVE EVALUATION

Formative evaluation answers the question, *Is the plan working?* As a result, it occurs *throughout* the implementation of an intervention. The purpose of formative evaluation is to determine the likely success of an intervention during its implementation so that it can be modified or changed to increase the likelihood that intended results will be achieved. The method to be used for formative evaluation should be detailed in the decision-making plan outlined during the plan implementation stage.

An effective formative evaluation method is to visually analyze the performance data during the intervention implementation and to compare these data to the baseline data collected prior to the intervention. Kazdin (1982) describes four visual analysis criteria that may be applied:

1. Change in mean: Is the average rate of performance higher (or lower) during the intervention than during baseline?

2. Change in level: Is there a discontinuity of performance (in the desired direction) from the end of baseline to the start of the intervention?

3. Change in trend: Does the trend in performance increase (or decrease) over time?

4. Latency of change: Is there a change in performance (in the desired direction) after the first week of intervention?

Another frequently used method is to examine the progress monitoring data in relation to the goal line using the four-point rule. If four consecutive data points are at or above the goal line, then the school psychologist and other problem-solving team members need to consider whether or not to raise the goal or, in some cases, how to program for maintenance and generalization so that exit can be discussed. If four consecutive data points fall below the goal line, then the school psychologist and other problem-solving team members need to decide how to change the pace of instruction, the materials being presented, the numbers of opportunities to respond, or the reinforcement in place, so that performance improves. If the data are highly variable, then the school psychologist and other problem-solving team members may need to decide how to motivate the student to more consistently perform the desired behaviors so that the data can then be evaluated against the goal line to determine the intervention effect.

TREATMENT INTEGRITY

The intervention needs to be implemented as planned in order to determine if the intervention is effective. The degree to which the intervention is implemented as planned is often called "treatment integrity" (Gresham, 1989; Telzrow, 1995; Yeaton & Sechrest, 1981). Several authors (e.g., Elliott, Witt, & Kratochwill, 1991; Fuchs & Fuchs, 1989; Lentz, Allen, & Ehrhardt, 1996; Reynolds et al., 1984; Taylor & Miller, 1997) have recognized the importance of treatment integrity in the implementation of an intervention.

There are a number of different approaches that can be used to assess treatment integrity. A teacher or parent may be interviewed regarding the steps followed during intervention (Kaufman & Flicek, 1995). Direct observation of teacher or parent behavior could be conducted occasionally throughout the intervention implementation to assess whether the steps are being carried out as planned (Gresham et al., 1993). Or the written step-by-step intervention plan could be used as a checklist; that is, every time the intervention was implemented the teacher or parent would complete the checklist to determine the steps that were followed (Gresham, 1989). The important component in assessing treatment integrity is determining the extent to which intervention procedures were implemented as intended.

Without at least occasional treatment integrity checks, the school psychologist cannot be sure that the intervention is being applied as designed (DuPaul & Stoner, 1994). If the intervention is not implemented as designed, progress (or lack thereof) cannot be attributed to the specific plan. It is a matter of internal validity; that is, regardless of size of effect, the school psychologist cannot conclude that changes in the dependent variable(s) (i.e., student behavior) can be attributed to the influence of the independent variable (i.e., intervention) if it has not been determined that the intervention was implemented as intended. School psychology practitioners who fail to monitor the consistency and accuracy with which interventions are implemented cannot validly attribute a student's behavioral improvements (or failure to improve) to the behavioral interventions implemented (Kaufman & Flicek, 1995).

There are strategies to ensure treatment integrity (Gresham, 1989; Rathvon, 1999): (a) have a written intervention plan (see intervention plan section), (b) train the student and implementers of the intervention, (c) build an observation component into the intervention plan, and (d) avoid complex and ecologically intrusive interventions because treatment integrity is negatively associated with the complexity and time required to implement interventions (Gresham, 1989; Yeaton & Sechrest, 1981).

SUMMATIVE EVALUATION

Summative evaluation answers the question, *Did the plan work?* As a result, it occurs *after* an intervention has been completed. The purpose of summative evaluation is to determine whether the intervention was successful and produced positive student outcomes. The school psychologist and other problem-solving team members should rely on two sources of information in conducing the summative evaluation: (a) the decision-making plan, particularly the decision rule, that was developed during the plan implementation stage and (b) the difference between the student's baseline performance and the post-intervention performance. In addition, it is recommended that data continue to be collected periodically to determine whether the progress is maintained once the intervention is removed (Casey et al., 1988). If there were positive outcomes, then the school psychologist along with other problem-solving team members can decide that the problem was resolved and plan for maintenance and generalization. If the outcome of the intervention was not positive, then the school psychologist and other problem-solving team members will want to consider changes to the intervention through reanalyzing the problem.

Innovation Configurations: Monitoring Your Practice

Recently, Telzrow, McNamara, and Hollinger (2000) found similar results to those found by Flugum and Reschly (1994) and Upah (1998): The majority of students are not receiving *quality* interventions. Telzrow et al. stress the need for the school psychology profession to increase the implementation of these quality indicators to improve the effectiveness of our interventions. One means of improving our practice is through self-monitoring of our skills. The innovation configurations presented in Figures 2–5 can assist with this self-monitoring.

An innovation configuration (Hord, Rutherford, Huling-Austin, & Hall, 1987) is a staff development tool that delineates for practitioners the skills related to the innovation in concrete, observable, and measurable terms. It presents "best" practice in operational terms while describing the variations in practice that may occur as practitioners apply new skills. School psychology practitioners can compare their own school-based interventions to these standards to examine the extent to which their practice meets quality intervention standards. This comparison allows for identification of current level of implementation and ways that school psychologists can improve provision of quality interventions.

Figure 2. Problem identification stage innovation configurations

Behavioral definition

5	4	3	2	1
Definition is (a) *objective*—refers to observable and measurable characteristics of behavior; (b) *clear*—so unambiguous that it could be read, repeated, and paraphrased by observers; and (c) *complete*—delineates both examples and non-examples of the behavior.	Definition meets only two of the three criteria (i.e., objective, clear, complete).	Definition meets only one of the three criteria (i.e., objective, clear, complete).	Problem behavior is stated in general terms (e.g., reading comprehension, aggressive behavior, etc.).	Behavioral definition is not written.

Baseline data

5	4	3	2	1
Data collected on the behavior *prior* to implementing the intervention consisting of repeated measures of the target behavior over several (at least three) sessions, days, or even weeks until a stable range of behavior has been identified.	Data collected on the behavior prior to implementing the intervention; however, only two data points are reported.	Data collected on the behavior prior to implementing the intervention; however, only one data point is reported.	Data collected on the behavior prior to implementing the intervention; however, the dimension(s) addressed are not the most appropriate for the selected target behavior.	Baseline data not gathered prior to implementing the intervention.

Problem validation

5	4	3	2	1
The magnitude of the discrepancy is quantified, based on a comparison between student's performance and the local educational setting demands.	The magnitude of the discrepancy is quantified, based on a comparison between the student's performance and standards outside the local educational setting.	The magnitude of the discrepancy is quantified, but is based on an opinion.	The magnitude of the discrepancy is described qualitatively.	Problem is not validated; magnitude of the discrepancy is not described.

Figure 3. Problem analysis stage innovation configuration

Problem analysis

5	4	3	2	1
Examined relevant and alterable factors from curriculum, instruction, environment, and student domains using a variety of procedures (RIOT: review, interview, observe, test) to collect data from a variety of relevant sources and settings. Used this information to develop a specific intervention to change the behavior.	Examined relevant and alterable factors from two to three domains only using two to three procedures to gather information. Used this information to develop a specific intervention to change the behavior.	Examined relevant and alterable factors from only the student domains using a variety of procedures (RIOT) to collect data from a variety of relevant sources and settings. Used this information to develop a specific intervention to change the behavior.	Examined relevant and alterable factors from the domains only using a variety of procedures to gather information from a variety of sources. However, there is no indication this information was used to develop a specific intervention to change the behavior.	Problem analysis is not conducted.

Innovation configurations are constructed in a standard way. A number of critical components of an innovation (in this case, quality interventions) are each scaled on an ordinal scale. For each component, variations on the left-hand side of the double line (usually designated as number 5) are considered to be the *best practice* application of a specific intervention component. Variations to the left of the single line are considered to be acceptable variations in application of the specific intervention component. Variations to the right of the single line (usually designated as number 3, 2, or 1) are considered to be unacceptable applications of the particular intervention component in that they may render the intervention ineffective.

SUMMARY

The qualifications and conclusions remain the same as those presented in Tilly and Flugum (1995). While it may appear that school-based interventions occur in a linear, well-articulated sequence, they do not. Many of the intervention components may occur simultaneously and many of the procedures cycle back upon themselves. The major point of this chapter is not to prescribe a lock-step order in which interventions are to be designed, implemented, and evaluated. Instead it is to use a familiar framework (i.e., behavioral consultation/problem-solving process) to illustrate how school psychology practitioners can ensure their own practice improves the quality of intervention practices, thus improving student outcomes.

As a school psychology practitioner, the first author acknowledges that interventions are almost never as pristine as are the procedures presented in chapters such as this one. Despite many challenges to our practice, however, using a problem-solving model to provide intervention services remains the best research-based approach for improving individual student outcomes. Whether students receive interventions through special education services or general education services, the components are equally applicable. Designing, implementing, and evaluating quality interventions will secure a place in future educational systems for school psychologists and more importantly result in improved outcomes for our students.

Figure 4. Plan implementation stage innovation configurations

Goal setting

5	4	3	2	1
Goal stated narratively and represented graphically on performance chart specifying time frame, condition, behavior, and criterion, which is based on a comparison between the student's baseline data and the expectations.	Goal represented graphically on performance chart specifying time frame, behavior, criterion, and condition—not stated narratively.	Goal stated narratively specifying time frame, behavior, criterion, and condition—not represented graphically.	Goal stated narratively and/or represented graphically on performance chart but does not specify all four components (time frame, condition, behavior, criterion).	Goal is not measurable or is not set.

Intervention plan

5	4	3	2	1
Plan stated (a) procedures/strategies, (b) materials, (c) when, (d) where, and (e) persons responsible.	Plan stated procedures/strategies. But one of the following components is missing: materials, when, where, or persons responsible.	Plan stated procedures/strategies. But two of the following components is missing: materials, when, where or persons responsible.	Generic description of intervention strategy (e.g., behavior management) is stated. Materials, when, where, and persons responsible may be present.	Intervention plan not written. Or generic descriptions of intervention (e.g., behavior management) only.

Measurement strategy

5	4	3	2	1
A measurement strategy is developed answering *how? what? where? who?* and *when?*	A measurement strategy is developed but only answers four of the five questions: *how? what? where? who?* and *when?*	A measurement strategy is developed but only answers three of the five questions: *how? what? where? who?* and *when?*	A measurement strategy is developed but only answers two of the five questions: *how? what? where? who?* and *when?*	Measurement strategy is not developed. Or the measurement strategy only answers one of the five questions.

Figure 4. (Continued)

Decision-making plan

5	4	3	2	1
The decision-making plan indicates (a) how frequently data will be collected, (b) the strategies to be used to summarize the data for evaluation, (c) how many data points or how much time will occur before the data will be analyzed, and (d) what actions will be taken based on the intervention data.	The decision-making plan indicates three of the four components.	The decision-making plan indicates two of the four components	The decision-making plan indicates only one of the four components.	The decision-making plan is not documented.

Figure 5. Plan evaluation stage innovation configurations

Progress monitoring

5	4	3	2	1
Data are collected and charted/graphed two to three times per week. Appropriate graphing/charting conventions were used (e.g., descriptive title, meaningful scale captions, appropriate scale units, intervention phases labeled).	Data are collected and charted/graphed once a week. Appropriate graphing/charting conventions were used.	Data are collected and charted/graphed irregularly and infrequently (less than once a week, but more than pre and post). Appropriate graphing/charting conventions may or may not be used.	Data are collected but not charted or graphed. Or only pre-information and post-information was collected and/or charted/graphed.	Progress monitoring data not collected.

Formative evaluation

5	4	3	2	1
There is evidence the decision rule was followed and visual analysis was conducted. These data were used to modify or change the intervention as necessary.	There is evidence the decision rule was followed and visual analysis was conducted, but the data were not used to modify or change the intervention as necessary.	Modifications or changes were made to the intervention based on subjective data.	Modifications or changes were made to the intervention, but no indication as to what data were used to make these changes.	No formative evaluation was conducted.

(Continued on the following page.)

Figure 5. (Continued)

Treatment integrity

5	4	3	2	1
Degree of treatment integrity measured and monitored. Plan is implemented as designed, including decision-making rules. Intervention changed/ modified as necessary on the basis of objective data.	Degree of treatment integrity addressed. Plan was implemented as designed and modified as necessary on the basis of subjective opinions.	Degree of treatment integrity addressed. Plan was implemented with variations from the original design with no basis for change stated.	Treatment integrity addressed, but intervention was not implemented as planned.	Treatment integrity not considered.

Summative evaluation

5	4	3	2	1
Outcome decisions are based on the progress monitoring data.	Outcome decisions are based on minimal data (i.e., pre and post tests).	Outcome decisions are based on subjective data.	Outcome decision stated but no indication of what data were used to make the conclusion.	No summative evaluation took place.

ANNOTATED BIBLIOGRAPHY

Bergan, J. R., & Kratochwill, T. R. (1990). *Behavioral consultation and therapy.* New York: Plenum.
This book presents a problem-solving model within the framework of behavioral consultation. The four stages include problem identification, problem analysis, plan implementation, and program evaluation. Each of these stages is developed through a structured interview with a primary goal of developing and evaluating effective interventions.

Howell, K., & Nolet, V. (2000). *Curriculum-based evaluation: Teaching and decision making.* Belmont, CA: Wadsworth/Thomason Learning.
This book provides the background information necessary to conduct CBE as well as specific decision-making frameworks for the areas of reading comprehension, decoding, language, written expression, math, social skills, and task-related behaviors. A model for generating hypotheses regarding the causes of student problems and procedures to validate those hypotheses is outlined for each area. Interpretation guides are provided to assist with linking the evaluation results to teaching recommendations.

Reschly, D., Tilly, W. D., III, & Grimes, J. (2000). *Special education in transition: Functional assessment and noncategorical programming.* Longmont, CO: Sopris West.
This book represents the work of various authors around the nation who have direct experience with special education reform. Chapters are included on functional analysis assessment, curriculum-based evaluation, system reform rationale and trends, and problem-solving system components.

Best Practices in Facilitating Intervention Adherence and Integrity

Cathy F. Telzrow and Jennifer J. Beebe
Kent State University

OVERVIEW

Intervention adherence is the degree to which an interventionist is committed to implement a specific treatment and actively demonstrates intervention-related behaviors (Meichenbaum & Turk, 1987). Related terms include *intervention fidelity* and *treatment integrity*, both of which refer to the degree to which a planned intervention is implemented as designed (Moncher & Prinz, 1991). Intervention adherence and integrity are critical for attributing student change to a specific intervention as well as for enhancing practitioners' ability to replicate and compare interventions across settings (Moncher & Prinz, 1991; Peterson & McConnell, 1996).

Despite the recognized importance of ensuring high levels of intervention adherence and fidelity as a means of enhancing outcomes for students, these key intervention elements are not well controlled for in either research or practice. Gresham, Gansle, Noell, Cohen, and Rosenblum (1993) examined a decade of published studies pertaining to school-based behavioral interventions, and reported that fewer than 15% evaluated and reported data concerning intervention fidelity. Similarly, investigations of pre-referral interventions in applied settings have reported that measures of treatment integrity are often absent (Telzrow, McNamara, & Hollinger, 2000).

Intervention adherence and integrity have relevance for a broad array of intervention contexts, including those directed toward individuals and families in medical, therapeutic, or counseling settings. This chapter discusses intervention adherence and integrity relative to academic and behavioral interventions in educational settings.

BASIC CONSIDERATIONS IN ENHANCING INTERVENTION ADHERENCE AND TREATMENT INTEGRITY

Intervention adherence and integrity can be enhanced by a series of professional decisions and actions. These include *selecting high probability interventions* and implementing these in ways that *promote intervention fidelity*.

High Probability Interventions

Theoretically, any treatment, including the nontraditional or ineffectual, can be implemented consistently and with good fidelity. However, maximizing positive outcomes for children's academic and behavioral functioning require that a combination of factors associated with the intervention and its implementation be present. The first of these is the selection of *high probability interventions*, meaning that they focus on keystone behaviors, have been empirically supported, and possess characteristics that cause them to be acceptable to interventionists and thus are more likely to be used.

FOCUS ON KEYSTONE BEHAVIORS

One of the first considerations when designing interventions is to select a behavior or skill that is critical for promoting behavioral change or enhancing the child's development (Gresham & Lopez, 1996; Lentz, Allen, & Ehrhardt, 1996). Such *keystone behaviors* are relevant to a specific disorder and can positively affect its course (Barnett, Bauer, Ehrhardt, Lentz, & Stollar, 1996). Such behavioral targets have been described as being *pivotal*, which means that when an identified target skill is enhanced, then improvements in a number of performance domains are evident. For example, for young children with autism, skills associated with motivation and responsivity to multiple cues are frequently targeted during intervention, since these are pivotal for developing other critical performances areas (Koegel, Koegel, & Carter, 1999). Additionally, keystone behaviors often produce positive collateral effects in teachers and parents. This means that by targeting a specific keystone behavior, the need for expensive, time-consuming, and complex interventions is reduced. A third characteristic of keystone behaviors is that they enhance positive instructional climates by reducing circumstances necessitating adverse interventions. For example, functional communication training is an important keystone behavior for students who exhibit self-injurious behavior, since this skill reduces the need for physical interventions (Carr & Durand, 1985).

EMPIRICALLY SUPPORTED

The second consideration in selecting high probability interventions is to choose a technique or procedure that has empirical support to improve the targeted behavior or skill. *Efficacious treatments* have been demonstrated to improve child performance or skill under highly controlled and often experimental conditions (Lonigan, Elbert, & Johnson, 1998). *Effective treatments* are those that have empirical support when implemented in applied settings, where high levels of internal control over the independent variables may not be possible (Lonigan et al., 1998). Experts generally recommend that the latter standard be employed when selecting high probability interventions, because it is more likely to be associated with higher levels of intervention adherence and fidelity (Lentz et al., 1996).

ACCEPTABLE TO INTERVENTIONIST

A third consideration in selecting high-probability interventions is the degree to which the treatment is acceptable to the interventionist. Some evidence suggests that treatment acceptability is an important variable in predicting intervention adherence and integrity (Elliott, Witt, & Kratochwill, 1991). As an example, Allinder and Oats (1997) examined teachers' acceptability toward the use of Curriculum-Based Measurement (CBM). They reported that teachers who rated CBM as highly acceptable administered CBM probes more frequently and set more ambitious goals for their students than did teachers who gave CBM low acceptability ratings. Furthermore, higher rates of implementation fidelity were associated with higher student math performance.

Other studies have reported findings that appear to contradict this relationship between intervention acceptability and implementation. For example, Turner, Watson, Watkins, Wildmon, and Little (in press) concluded that intervention acceptability may not predict high levels of treatment fidelity. Similarly, Peterson and McConnell (1996) reported that teacher ratings of intervention acceptability were weak predictors of intervention integrity among their sample of early childhood special education teachers. One reason for this finding may be that the teachers' acceptability ratings were obtained before the implementation of the intervention. It has been suggested that actual use of a specific treatment in an intervention setting is a better indicator of treatment acceptability than pretreatment ratings (Gresham & Lopez, 1996; Witt, 1997). Similarly, Odom, McConnell, and Chandler (1993) caution that teachers may rate interventions as acceptable, but not feasible, and the latter index is a better predictor of actual use.

Despite those recent findings and evolving conceptualizations of intervention acceptability, several factors have been shown to influence intervention acceptability, as well as subsequent levels of treatment adherence and fidelity. What follows is a brief description of the major elements associated with treatment acceptability, including ease of implementation, positiveness, perceived effectiveness, and consistency with the intervention setting.

Easy to Implement. A number of studies have reported that intervention adherence and integrity are enhanced when the interventions selected are easy to implement. Martens, Peterson, Witt, and Cirone (1986) found that teachers prefer treatments they can implement independently to those requiring consultation with others. Gresham (1989) reported that complex treatments requiring large amounts of time and materials or numbers of staff members to implement usually are not delivered with the same fidelity as those that are less involved. Lentz et al. (1996) concluded that "the more complex and time-consuming the intervention, the less likely it will be implemented as intended" (p. 129).

Although there is considerable support for those conclusions, exceptions do exist. For example, teachers appear willing to implement even complex interventions when the student's problem is severe (Elliott et al., 1991). Additionally, consultant coaching and support have been shown to enhance intervention adherence and treatment integrity even when the method used is complex (Northup et al., 1994). In a recently published article examining treatment integrity in educational programs for children with autism, Dietrich (1999) suggested that there might be occasions when an intervention has low acceptability but high fidelity. He suggests that such situations be examined to determine how fidelity may be affected when consultation is discontinued or how ratings of acceptability may change when a difficult-to-implement intervention is associated with significant student improvement.

Positive. A second characteristic of the intervention plan that may affect treatment acceptability, and therefore adherence, is the degree to which it is perceived as educative or positive. Clark and Elliott (1988) reported that teachers consistently favored interventions that employed positive (e.g., modeling, coaching) strategies over those that were perceived as punitive or aversive (e.g., overcorrection). Although teacher acceptability toward a negative intervention (i.e., exclusionary time out) has been reported to be higher than that of school psychologists or school social workers, all groups rated a positive intervention (i.e., token economy program) as more acceptable (Fairbanks & Stinnett, 1997). Furthermore, interventionists appear to maintain this preference for positive treatments and to judge these as more effective than other methods, even when provided with outcome data suggesting comparable results across treatments (Bihm, Sigelman, & Westbrook, 1997). Recent studies have suggested that acceptability ratings can be influenced by interventionists' exposure to the target individual and behavior, including through video vignettes (Foxx, Bremer, Shultz, Valdez, & Johndrow, 1996).

Perceived Effectiveness. Although the actual effectiveness of a specific treatment cannot be determined without a satisfactory trial of implementation, *perceived effectiveness* has been shown to relate to intervention acceptability. Perceived effectiveness refers to the degree to which the interventionist believes that the treatment is likely to address the identified concern. Lentz et al. (1996) assert that "change targets and goals must either directly overlap with the personal reasons for referral by the problem presenter, or problem solvers will need to logically persuade problem presenters to accept them" (p. 135).

Matches Intervention Context. Dietrich (1999) has suggested that the degree of compatibility between the intervention demands and the characteristics of the instructional environment can influence intervention integrity. Similarly, Lentz et al. (1996) contend that one characteristic of strong school-based interventions is that they are minimally disruptive to the classroom ecology. Furthermore, there is evidence that these contextual influences are bi-directional. For example, McConnachie and Carr (1997) reported that certain interventions (e.g., escape extinction) produce child behaviors that are punishing to teachers' efforts to maintain the treatment, and, in such circumstances, treatment integrity deteriorates over time.

Dietrich's (1999) discussion of these contextual considerations encompasses child and staff characteristics, as well as features of the intervention and the treatment setting. Other contextual factors that should be considered when choosing interventions include (a) the resources that are required for treatment, and the degree to which these are available in the instructional setting; (b) the consistency between the interventionist's training and the demands of the treatment; and (c) the characteristics of the child and how these might be related to intervention acceptability and treatment integrity (Dietrich, 1999).

Elements That Can Enhance Implementation Fidelity

Once high probability interventions have been identified and selected, the challenge lies in ensuring that these interventions are implemented correctly. Several practices can enhance intervention adherence and integrity, including the use of intervention scripts or treatment manuals, opportunities for guided practice and feedback, and the integration of treatment integrity checks and intervention monitoring.

INTERVENTION SCRIPTS OR TREATMENT MANUALS

One recommended method for enhancing intervention fidelity is the introduction of intervention scripts or treatment manuals into the implementation process. Such techniques are designed to provide interventionists a step-by-step protocol to follow during the implementation of the treatment. Intervention scripts that are collaboratively created, ecological in scope, and written using concrete and practical language have been rated by teachers and parents as acceptable, nonintrusive, and easy to use within daily routines (Ehrhardt, Barnett, Lentz, Stollar, & Reifin,1996). The use of scripts during intervention implementation also has been directly related to positive treatment outcomes (Ehrhardt et al., 1996; Hirallal & Martens, 1998).

Although Ehrhardt et al. (1996) suggest that scripts should be developed collaboratively with those intended to implement the intervention, more pragmatic considerations in script creation have been identified by other experts. Gottfredson (1993) and Moncher and Prinz (1991) emphasize the clear specification of implementation standards, including the quantity and quality of services to be provided, as well as any activities related to the implementation of intervention components. Moncher and Prinz (1991) suggest that intervention manuals must strike a balance between structure and flexibility, such that the interventionist is able to follow specific procedures while also adapting the intervention to meet the needs of the client. In addition, they recommend that treatment protocols must meet an intermediate level of specificity so that the procedures are neither too overwhelming to facilitate adherence nor too vague to implement with integrity.

GUIDED PRACTICE AND FEEDBACK

Opportunities for guided practice and feedback are additional factors in the facilitation of treatment fidelity. Even when provided with intervention scripts and knowledge from treatment manuals, interventionists may lack the skills to apply intervention techniques appropriately in the absence of opportunities for practice. Hirallal and Martens (1998) demonstrated the positive effects of teacher training on treatment fidelity in a study designed to teach classroom management skills to preschool staff. Their results implicated training methods such as modeling, role-play, and observation with feedback as instrumental in promoting treatment integrity.

In the absence of feedback, intervention implementation activities may substantially decrease. For example, McConnachie and Carr (1997) found higher levels of treatment integrity when the interventionist was guided by a "Bug-In-The-Ear" device, which permitted coaching to occur within the actual intervention setting through a hearing aid–type intercom system. Similarly, Jones, Wickstrom and Friman (1997) reported that consultation paired with performance feedback significantly increased treatment integrity levels over the provision of consultation alone. Finally, Mortenson and Witt (1998) demonstrated that weekly performance feedback from consultants increased levels of treatment integrity for teachers previously receiving little support.

In a 3-year program targeting behavioral problems in middle schools, Gottfredson (1993) found that the provision of effective feedback can vary in source from administrators to consultants to peers, as well as in frequency, from daily to weekly to periodic. Overall, providing a variety of opportunities for practice and feedback, as well as periodic booster sessions, can facilitate and help to maintain intervention adherence and treatment integrity (Moncher & Prinz, 1991).

TREATMENT INTEGRITY CHECKS/INTERVENTION MONITORING

A final strategy for promoting treatment adherence and integrity involves the incorporation of treatment integrity checks and intervention monitoring devices. In his critique of common assumptions concerning school-based consultation, Witt (1997) cautioned that practitioners should not assume that there is a correspondence between talking and doing or that talk produces change in behavior. Instead, he maintains that direct assessment of intervention adherence is required. Some methods of monitoring intervention activity include participant reports, outside sources, and evaluation of permanent products (Gottfredson, 1993; Moncher & Prinz, 1991).

There is a need to evaluate the perceptions of participants through self-reports to assess their understanding of the treatment and its progress (Moncher & Prinz, 1991). Although self-report data are often used to evaluate treatment integrity, there are limitations to this approach. For example, Wickstrom et al. (1998) reported significant discrepancies between levels of treatment fidelity reported by teachers (54%) and revealed by direct observation (4%). Such findings suggest that external sources may be preferred for the collection of reliable treatment integrity data.

Objective data collected from outside sources are described as the most useful in documenting intervention adherence and treatment integrity (Moncher & Prinz, 1991). Suggested practices for treatment integrity checks include using multiple observers who are adequately trained in data collection and coding as well as gathering multiple behavior samples to insure the representativeness of the data (Moncher & Prinz, 1991).

Review of existing records, such as service logs, activity sheets, and intervention scripts, also can provide data useful for evaluating the degree to which an intervention has been implemented as planned (Ehrhardt et al., 1996; Gottfredson, 1993; Hirallal & Martens, 1998; Jones et al., 1997).

The process of fusing high probability interventions with correct implementation is essential for effective school-based consultation. According to Witt (1997), these guidelines for practice may assist in bridging the gap between teachers' agreeing to an intervention (talk) and actually implementing that intervention (action). First, suggest interventions based on research (*high probability interventions*). Second, identify specific elements embodied within the intervention and create a checklist of these (*intervention script*). Next, provide participants with opportunities for training and support (*guided practice/feedback*), and monitor for accurate implementation (*treatment integrity checks*). Implementation of these guidelines is illustrated by the following best practices for facilitating intervention adherence and treatment integrity.

BEST PRACTICES IN ENHANCING INTERVENTION ADHERENCE AND INTEGRITY

As was illustrated by the basic considerations just reviewed, certain professional decisions and actions can enhance intervention adherence and integrity. These have been captured in nine professional practice recommendations concerning the selection of interventions and the conditions surrounding their implementation (Table 1). Research suggests that optimal outcomes for children's academic or behavioral concerns are derived from interventions that focus on keystone behaviors, have demonstrated efficacy, and are acceptable to interventionists. In addition to selecting high probability interventions, it is possible to enhance the fidelity of their implementation by using intervention scripts or treatment manuals, incorporating guided practice and feedback, and providing for treatment integrity checks or intervention monitoring. Specific best practice strategies that address these various components are described in the following sections.

Choose High Probability Interventions

CHOOSE INTERVENTIONS THAT ADDRESS KEYSTONE BEHAVIORS

Target goals for students should pass the "so what?" test, meaning that the identified skill or behavior warrants addressing in their educational program because acquiring the target behavior contributes to enhanced functioning (Kaplan, with Carter, 1995). Although it is often easier to target circumscribed, easily evaluated skills in a child's Individualized Education Program (IEP), such goals often don't pass the "so what?" test because they are trivial and unimportant for achieving meaningful educational progress. In contrast, preferred keystone behaviors broadly enhance the child's present and future functioning (Barnett et al., 1996). Three examples of keystone behaviors for children's school-based referrals that have been described by Barnett et al. (1996) are compliance training, communicative functions of behavior, and rule-governed behavior and self-regulation. Other examples, as well as non-examples, are included in Table 1.

CHOOSE INTERVENTION APPROACHES THAT HAVE EMPIRICAL SUPPORT

Despite the obvious importance of selecting treatment approaches that have been demonstrated to address identified needs, the use of unproven methods is a continuing concern in educational interventions (e.g., Cohen, 1998; Fuchs, 1991). A complete description of empirically supported interventions for children's academic and behavioral targets is beyond the scope of this chapter. However, a comprehensive

Table 1. Intervention elements that can enhance treatment adherence and integrity

Intervention element	*Definition*	*Examples*	*Non-examples*
Intervention focuses on keystone behavior	Behavior represents core performance domain that can enhance child's development and functioning	•Communication skill •Attention •Eye contact	•Bead stringing •Figure copying
Intervention has evidence of empirical support	The intervention has been shown to produce desired changes in academic or behavioral functioning when implemented in applied setting	•Phonemic awareness training •Functional communication training •Cognitive behavioral interventions for internalizing disorders	•Facilitated communication •Vision training as a reading intervention
Interventions are easy to implement	Interventions can be implemented without additional training, materials, or staff members	•Response cost •Contingency contracting	•Self-management •Class-wide peer tutoring
Interventions are positive	Interventions rely on constructive, educative approaches rather than those that are corrective or punitive	•Functional communication training	•Exclusionary time out •Escape extinction
Interventions have perceived effectiveness	Interventions are judged by the interventionist to address the specified concern	•Home-notes when homework completion attributed to insufficient parent supervision	•Curriculum-based measurement in instances where data not used to make teaching changes
Interventions are matched to contextual variables	Intervention matches resources, staff experience, and treatment philosophy of instructional environment	•Peer-assisted social and language interventions in an inclusive, developmentally appropriate preschool	•Discrete trial training in a developmentally appropriate preschool
An intervention script or treatment manual is used	Detailed intervention protocol, including specific verbiage and alternative responses	•See Table 2 for example	•An intervention that is identified only by a title or cursory description
Guided practice and feedback are provided to the interventionist	Ongoing technical assistance from a consultant during the intervention period	•Videotape or live models •Corrective feedback during implementation	•Interventionist implements intervention with no feedback or assistance
Treatment integrity checks or intervention monitoring systems are employed	Methods to document accurate implementation of the intervention	•See Figure 2 for example •Permanent products	•Absence of objective data about accurate implementation

initiative to inform practitioners about such interventions is currently in progress (Kratochwill & Stoiber, 2000). A Task Force on Empirically Supported Interventions in Schools, jointly supported by the American Psychological Association/Division 16 and the Society for the Study of School Psychology, began to compile published findings concerning empirically supported school-based interventions in 1999. Members of the Task Force, which is co-chaired by Tom Kratochwill and Karen Callan Stoiber, are identifying effective school-based prevention programs, school-based intervention programs for social behavior problems, academic intervention programs, and school-wide and classroom-based programs. It is anticipated that the ongoing work of the Task Force will be published in a variety of professional outlets, including a standing section on empirically supported interventions in *School Psychology Quarterly*.

CHOOSE INTERVENTIONS THAT ARE EASY TO IMPLEMENT

As was noted earlier, the literature on intervention acceptability has consistently reported that teachers favor interventions that are easy to implement over those that are more complex. However, ease of implementation is relative, since judgments about a treatment's complexity may be influenced by the nature of the student's problem, by the interventionist's training and experience, by the influence of the consultant, or by the material and human resources available within the intervention setting (Dietrich, 1999; Elliott et al., 1991; Graham, 1998). Despite the effects of such factors, in general treatment adherence and integrity are enhanced when an intervention is feasible, given the interventionist's skills and access to personal and systemic supports (Odom et al., 1993). A brief checklist or questionnaire can be used to ascertain the degree to which the teacher considers a proposed intervention acceptable because of implementation ease. Examples of such devices include the Abbreviated Acceptability Rating Profile (Tarnowski & Simonian, 1992) and the Intervention Rating Profile-15 (Martens, Witt, Eliott, & Darveaux, 1985). Single-item teacher ratings of intervention feasibility and ease of implementation also have been used (Fuchs, 1991; Odom et al., 1993).

CHOOSE INTERVENTIONS THAT ARE POSITIVE

Research has consistently identified a preference for constructive and educative treatments over those that are reductive or eliminative among interventionists in a wide array of settings (Elliott et al., 1991). Although there is evidence that aversive interventions are effective in addressing serious challenging behaviors (Mulick, 1990) and that exposing interventionists to individuals for whom such approaches are being considered enhances their acceptability ratings (Foxx et al., 1996), situations requiring such methods are likely to be rare. For this reason, as well as professional practice guidelines opposing the use of aversive interventions (Meyer & Evans, 1989), the selection of positive, educative interventions is recommended.

CHOOSE INTERVENTIONS THAT HAVE PERCEIVED EFFECTIVENESS

An additional professional practice suggestion that can enhance treatment adherence and integrity concerns the selection of treatments that are perceived as effective by the interventionist. This guideline suggests that the chosen intervention approach must be consistent with the teacher's beliefs about what is maintaining the problem, as well as his or her judgment about its potential to remedy that concern (Lentz et al., 1996). Fuchs (1991) refers to this as the degree to which interventionists view the proposed treatment as "worthwhile." During his work with pre-referral intervention teams, teachers were asked to rate proposed interventions on a 4-point scale, where "1" meant "not at all worth doing," and "4" meant "definitely worth doing." Use of a similar brief rating may assist in determining the perceived effectiveness of proposed interventions in school-based consultation settings.

CHOOSE INTERVENTIONS THAT MATCH THE TREATMENT SETTING

Intervention adherence and integrity are enhanced when the intervention disrupts the ecology of the treatment setting as little as possible (Lentz et al., 1996). In addition, interventions that are consistent with the philosophical approaches and training experiences of the staff also are likely to be implemented with greater fidelity (Dietrich, 1999). Dietrich (1999) provided several practical tools to assist in evaluating this match between the characteristics of the intervention and the treatment settings. These include observational systems to determine the frequency, timing, and individual targets of teacher-student interactions and descriptive analyses of instructional variables related to individual versus group setting, skills taught, and frequency of responses. According to Deitrich, "matching intervention to contextual variables in the classroom is valuable in ensuring treatment fidelity and success" (p. 617).

Incorporate Conditions to Enhance Treatment Fidelity

EMPLOY AN INTERVENTION SCRIPT OR TREATMENT MANUAL

As was noted earlier, it is not uncommon for interventionists to have high levels of commitment and enthusiasm about a given intervention, and to be actively engaged in implementing the chosen strategy, but to have poor levels of intervention integrity because of an inaccurate or incomplete understanding about how to implement it correctly. The use of intervention scripts or treatment manuals provides one remedy for this situation by providing teachers with a clearly detailed description of the chosen intervention.

Intervention scripts provide a step-by-step description of the treatment procedure. These are intended to incorporate sufficient detail to direct the accurate implementation of the strategy or technique, including what interventionists should say and how they should respond to a range of circumstances during the course of implementation. The potency of intervention scripts and treatment manuals for facilitating intervention fidelity has been demonstrated for a variety of interventions across diverse settings. The literature describing well-established and probably efficacious psychosocial interventions for childhood disorders recommends the use of treatment manuals as a mechanism for enhancing reliable implementation of the prescribed treatments (Lonigan et al., 1998). Fuchs (1991) reported that the addition of intervention scripts illustrating specific step-by-step guidelines for implementing contingency contracts and interval recording enhanced the fidelity of these prereferral interventions. Other studies have demonstrated the value of scripts for enhancing consistent application of contingent praise for preschool children (Martens & Hirallal, 1997), parent implementation of bedtime routines (Ehrhardt et al., 1996), and behavioral interventions to improve children's attending during small group art activities (Hiralall & Martens, 1998).

An example of an intervention script is contained in Table 2. This sample delineates the specific steps for implementing a response cost intervention to enhance hand raising and teacher recognition before speaking during circle time in a kindergarten classroom. Once the elements of the detailed intervention script are well understood by the interventionist, a flow-chart summarizing the procedure in graphic form may be used to provide a useful and abbreviated reference (Figure 1).

Table 2. Sample intervention script for response cost

Response cost is an effective strategy for assisting young children's acquisition of group/classroom skills. The response cost system involves allotting points to children at the beginning of a designated period and subsequently removing points for each instance of inappropriate behavior. A reward is given based on the number of points remaining at the end of the period. What follows is an example of how this intervention may be used to reduce calling out/speaking out of turn in a kindergarten classroom.

Step 1. Before Circle Time, make sure that the Hands Up chart has 10 cardboard silhouettes of hands on it.

Step 2. Begin instruction by showing the class that they have 10 hands on their chart, and remind them that they will need at least 3 hands on the chart after Circle Time in order to get free time later in the day.

Step 3. Remind the children to raise their hands and wait to be called on before answering.

Step 4. If a child raises his/her hand and waits to be called on, make eye contact and say, "Name, I like the way you raised your hand and waited to be called on!"

Step 5. Tally the total number of times verbal praise is given. ____________________

Step 6. If a child calls out without raising his/her hand and being called on, look at the child and say, "Name, you need to raise your hand and wait to be called on."

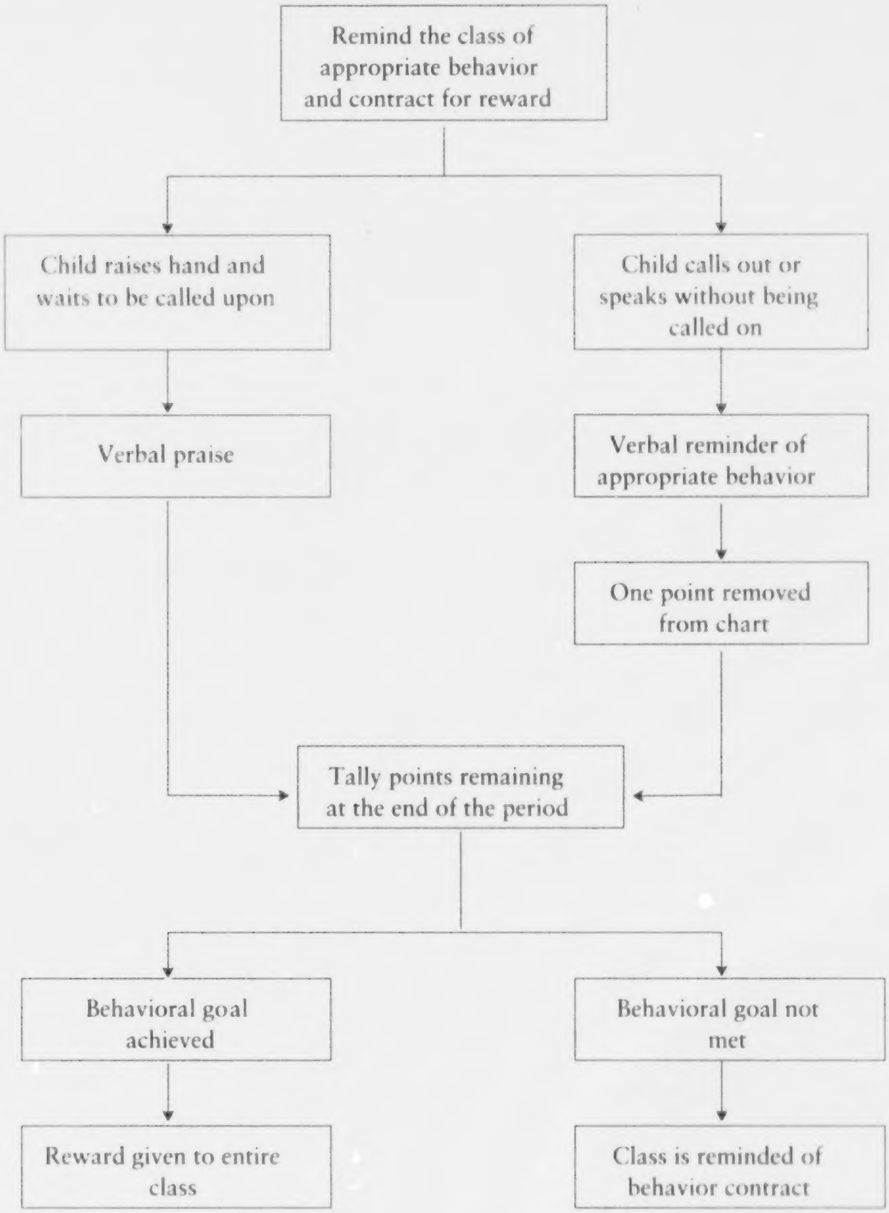
Step 7. Ask the child to remove one of the hands from the Hands Up chart.

Step 8. At the end of Circle Time, ask the children to look at their chart and count the number of hands left. (Number of hands left: ________)

Step 9. Either reward the class with 15 minutes of free time or remind the class that they will need to improve raising their hands and waiting to be called on so that they can earn free time tomorrow.

Step 10. Refer to the intervention script on fading response cost when the class earns free time consistently.

Figure 1. Flow chart of response cost intervention script



Remind the class of appropriate behavior and contract for reward
Child raises hand and waits to be called upon
Child calls out or speaks without being called on
Verbal praise
Verbal reminder of appropriate behavior
One point removed from chart
Tally points remaining at the end of the period
Behavioral goal achieved
Behavioral goal not met
Reward given to entire class
Class is reminded of behavior contract

PROVIDE GUIDED PRACTICE AND FEEDBACK

Even with the use of high probability interventions and an intervention script, interventionists may require guided practice, feedback, and coaching to produce consistent levels of implementation fidelity in actual settings. One arena for enhancing implementation fidelity in school-based settings is student-centered consultation, provided to an individual teacher or members of an educational team (Conoley & Gutkin, 1995). The success of this method for facilitating teacher change has been thought to be related to the consultant's influence, which may be derived from several bases. According to Erchul and Raven (1997), interventionists may be persuaded to persist in implementing a treatment because the consultant is perceived as having expert influence (i.e., they appear knowledgeable and credible). Additionally, an interventionist may be influenced by the referent qualities of the consultant, meaning that they are likeable and interact in a collaborative manner with the interventionist. Other possible sources of influence include the consultant's ability to coerce or reward, to employ legitimate power by virtue of position, or to influence through the use of information (Erchul & Raven, 1997).

O'Keefe and Medway (1997) suggest that one reason for teacher "resistance" to implement an intervention is that they believe they are unable to do so, either as a result of generalized self-efficacy deficiencies or because of reasons that are situation-specific. Some research suggests that this impediment to intervention implementation may be addressed by providing vicarious models and verbal persuasion. Specifically, Hagen, Gutkin, Wilson, and Oats (1998) reported that pre-service teachers who were shown videotape vignettes of teachers successfully implementing behavioral techniques with challenging students had higher self-efficacy scores in the areas of personal teaching and classroom management than control teachers who viewed a placebo videotape. These findings suggest that published programs that incorporate video vignettes demonstrating the use of specific interventions (e.g., Beck, 1996) could be employed to enhance implementation fidelity.

Despite the persuasive arguments of Conoley and Gutkin (1995), others have suggested that exclusive reliance on indirect methods of teacher technical assistance through consultation may impede optimal levels of implementation fidelity (e.g., Jones et al., 1997; Watson & Robinson, 1996; Witt, 1997). Watson and Robinson (1996) have proposed the use of direct behavioral consultation, in which skills are taught to interventionists by using direct instruction strategies. In this method the consultant explains the procedure to the interventionist, models its use with the target student, and remains available to give corrective feedback as teachers begin the implementation process. Hirallel and Martens (1998) employed a five-step teacher training process consisting of (a) a description of the technique, (b) demonstration, (c) practice, (d) feedback, and (e) application in the instructional setting. Corrective feedback occurred during individual conferences and consisted of specific praise for accurate implementation and explicit models for improving accurate implementation. Jones et al. (1997) described a feedback procedure that incorporated a rationale for its use, data summaries of implementation fidelity and student responses, and an explanation of ways to improve integrity. It has been suggested that direct instruction methods of providing technical assistance may be particularly effective when the intervention is complex or when interventionists have restricted specialized knowledge (Hiralall & Martens, 1998; Northup et al., 1994; Watson & Robinson, 1996). The use of periodic booster sessions to ensure continued accuracy of implementation following initial mastery of an intervention also has been recommended (Moncher & Prinz, 1991).

EMPLOY TREATMENT INTEGRITY CHECKS

Because of the tendency for accurate implementation to deteriorate over time, incorporating explicit treatment integrity checks is recommended. A variety of methods may be employed, including self-monitoring strategies, external observational systems, examination of permanent products, and program-wide fidelity checks.

Self-monitoring and external observational systems typically utilize a checklist of the major intervention elements, together with a rating scale on which the interventionist can record whether or not each was implemented. An example of a treatment integrity check for the response cost intervention described earlier is depicted in Figure 2. Although self-monitoring systems have the advantage of being nonintrusive and relatively easy to use, some data suggest that interventionists may overestimate their rates of fidelity when using such systems (e.g., Wickstrom et al., 1998). For this reason, more objective measures of implementation fidelity, such as external observations or the use of permanent products, are recommended. In addition, employing multiple observers and sampling across implementation sessions is suggested (Moncher & Prinz, 1991).

Many interventions are conducive to the use of permanent products as a source for documenting treatment integrity. For example, daily home notes to parents, assignment completion recording systems, and daily journaling activities all incorporate written

Figure 2. Sample treatment integrity check for response cost

Teacher: ____________ Date: __________ Day: M T W Th F

Instructions: For each step in the intervention, check "Y" if the step is completed or "N" if the step is not completed.

Intervention steps	Y	N
Checked that Hands Up chart has 10 cutout hands before Circle Time.		
Remind class of the Hands Up chart and behavioral contract.		
Remind class of the appropriate behavior (raise hand and wait to be called on).		
Praise children individually for appropriate behavior.		
Tally total number of times children are praised for the appropriate behavior. ______________		
When calling out/speaking out of turn occurs, remind child of appropriate behavior and direct child to remove one hand from the Hands Up chart.		
Count the number of hands left on the chart immediately following Circle Time. ________________		
Provide the class with a reward if more than three hands remain. OR Remind the class of the behavioral contract if less than three hands remain.		

records that can be collected and evaluated for their frequency and completeness of implementation.

Comprehensive systems to track intervention fidelity within programs and agencies have been described by Gottfredson (1993) and LaVigna, Willis, and Sweitzer (1990). In these approaches the program components determined to be critical for producing student improvement are described and standards of implementation are specified. Data regarding implementation fidelity are collected through permanent products or external observation. When discrepancies between specified performance standards and actual implementation are identified, these signal the need to intervene in the system to enhance implementation fidelity.

SUMMARY

This chapter has identified practices that can enhance intervention adherence and integrity. These include (a) targeting socially valid behaviors; (b) addressing these through interventions that have empirical support, as well as other characteristics that increase the probability that they will be implemented (e.g., easy to use, positive, perceived to be effective, and matched to the intervention context); (c) employing an intervention script to increase reliable implementation; (d) providing feedback and technical assistance to interventionists; and (e) incorporating treatment integrity checks. The relative contributions of these practices to maintaining satisfactory levels of implementation fidelity are unknown. However, since some recent research has suggested that combining approaches may produce the highest levels of treatment integrity (e.g., Hiralall & Martens, 1998), incorporating as many of these practices as possible is recommended.

ANNOTATED BIBLIOGRAPHY

Dietrich, R. (1999). Increasing treatment fidelity by matching interventions to contextual variables within the educational setting. *School Psychology Review, 28*, 608–620.
This article describes a method of enhancing treatment fidelity by matching intervention characteristics to contextual variables such as classroom culture, student-teacher interactions, and available resources. Practical systems for assessing instructional environments in order to improve the "goodness of fit" between the intervention and the instructional ecology are included.

Hiralall, A. S., & Martens, B. K. (1998). Teaching classroom management skills to preschool staff: The effects of scripted instructional sequences on teacher and student behavior. *School Psychology Quarterly, 13*, 94–115.
Multiple approaches to treatment adherence and integrity principles were implemented with teacher-student dyads. The results support the use of direct instruction sequences and intervention scripts in teacher training, and implications for school psychology practice are discussed.

Lentz, F. E., Jr., Allen, S. J., & Ehrhardt, K. E. (1996). The conceptual elements of strong interventions in school settings. *School Psychology Quarterly, 11*, 118–136.
This article provides an excellent discussion of many of the practices discussed in this chapter, including socially valid and empirically supported interventions, treatment acceptability, and achieving a match between the intervention and the instructional ecology. Tables provide useful summaries of characteristics of strong school-based interventions for both academic and behavioral concerns.

Moncher, F. J., & Prinz, R. J. (1991). Treatment fidelity in outcome studies. *Clinical Psychology Review, 11*, 247–266.
This review of psychosocial treatment outcome studies during the decade of the 1980s provides an excellent discussion of factors related to intervention and integrity. This first-rate foundational reference addresses such practices as treatment manuals, supervision of treatment agents, and integrity monitoring checks.

Watson, T. S., & Robinson, S. L. (1996). Direct behavioral consultation: An alternative to traditional behavioral consultation. *School Psychology Quarterly, 11*, 267–278.
An alternative to traditional consultation—*direct behavioral consultation*—is proposed. The authors provide a detailed rationale for pursuing a more active approach to consultation, along with descriptive examples of how model can be implemented in school-based settings. Future directions for research of this model are also discussed.

35 Best Practices in Evaluating Interventions

F. Charles Mace
University of Wales

OVERVIEW

School psychologists and educational teams make critical decisions that significantly affect the lives of students and their families. Decisions based on subjective and anecdotal report alone may result in ineffective or harmful interventions and/or the discontinuation of otherwise effective interventions. Decisions based on accurate, reliable, and socially meaningful data allow the team to make informed decisions that result in positive and significant behavioral change. The collection and analysis of meaningful data positively influence the effectiveness and interventions. For example, Fuchs and Fuchs (1986) found that teachers were more effective and efficient in their delivery of instructional programs when educational decisions were based on student performance data instead of subjective teacher judgment. Student performance data (e.g., increased reading comprehension, increased prosocial behavior, decreased aggressive behavior, decreased oppositional behavior) are the measured results of interventions orchestrated by the educational team. These data directly document behavior change and, indirectly, document the performance of the professional(s) responsible for planning and implementing the intervention.

On one level it may be enough to know that the behavior of a student changed for the better upon implementation of an intervention. However, a best practices approach to the evaluation of the effectiveness of interventions requires a demonstration of a functional relationship between the intervention and the resulting data (Steege, & Wacker, 1995). When practitioners show that a specific intervention causes a behavior to change, a functional relationship between the procedure and the target behavior(s) is demonstrated. A functional relationship is established when (a) the target behavior changes when an independent variable (an intervention) is manipulated, while all other variables are held constant, and (b) the process is replicated or repeated one or more times and the behavior changes each time (Miltenberger, 1997).

A best practices approach to the evaluation of the efficacy of interventions involves the use of single-case experimental designs to demonstrate a functional relationship between the intervention and the behavioral measures. By using single case experimental designs, the school psychologist is able to demonstrate that the intervention was responsible for the measured change in behavior and rule out the possibility that confounding variables caused the behavior to change. The following sections will discuss several issues that are critical to the measurement of intervention outcomes and to the validation of functional relationships.

Single-Case Experimental Designs

Unlike group research designs, which include an experimental and control group, single-case experimental designs involve the study of a single unit before, during, and following the introduction of an intervention. The unit of analysis may be one student in the classroom or a group of students in a third-grade classroom (Lundervold & Belwood, 2000). Single-case experimental methodology does not rely upon statistical tests to determine the significance of interventions. Rather, the data for each subject (or unit) are displayed in a graph that can be visually inspected to analyze the impact of the intervention on the target behavior (Polaha & Allen, 1999).

Why Single-Case Experimental Designs?

Polaha and Allen (1999) and Steege and Davin (2000) have identified a number of reasons why single-case experimental design is a best practices approach for evaluating the effectiveness of interventions:

1. Collecting data on a single subject versus groups of subjects is cost effective
2. Data can be analyzed without the use of complicated statistics
3. Objective determination of student progress is documented
4. Ongoing evaluation of interventions allows the team to quickly identify effective and ineffective components and to make necessary adjustments to the interventions
5. Practitioners have an ethical responsibility for evaluating the efficacy of interventions
6. Federal, state, and agency regulations require documentation of intervention effectiveness

Single-case experimental designs control for threats to internal validity (and render rival hypotheses less plausible) in the following ways: (a) They establish within-condition (baseline) variability in the student measures via repeated assessment, (b) they introduce an independent or intervention variable, (c) they document the effects of the intervention through repeated measurement, and (d) they replicate the intervention effect via repetition of the baseline and intervention conditions. When both the introduction and the withdrawal of the intervention results in behavior change, a functional relationship between the intervention and the student's behavior change is demonstrated. Moreover, the introduction and/or withdrawal of the intervention must result in a relatively immediate impact on trends in the student's behavior. Finally, when the student's behavior change is replicated, one can be more certain that the intervention resulted in the desired behavior change. With single-case designs, replication is demonstrated with the individual student across time, settings, behaviors, or personnel. In addition, the intervention may be replicated across students or similar behaviors (Steege, & Wacker, 1995).

BASIC CONSIDERATIONS

Stages of Evaluation

Evaluating interventions is a process. While at some level this process often begins at the point of referral for assessment and intervention, for the purposes of this chapter we are introducing the stages of evaluation that would be used after functional assessment has been conducted and the team has collaborated in the design of an intervention. Within our model, the evaluation process consists of five stages: (a) defining and recording behaviors, (b) selecting a design, (c) collecting baseline data, (d) implementing the intervention and ongoing collection of data, and (e) analyzing results (see Figure 1). Each stage will be described, and examples of best practices for evaluating interventions will be provided.

Defining and Recording Behaviors

The initial step in evaluating the effectiveness of an intervention involves identifying and describing the behaviors that are expected to change as a function of the intervention. Specifically, the school psychologist needs to develop unambiguous and concise definitions of target behaviors. Behaviors need to be described in a way that is understandable to all members of the team. Specifically, this means that after reviewing a written description of a target behavior, two observers should be able to observe a student and agree that the target behavior occurred. As a general rule, a description of behavior should meet three criteria: objectivity, clarity, and completeness (Kazdin,

1994). To be *objective*, the description of behavior should refer to observable features. To be *clear*, the definition should be so unambiguous that it can be accurately repeated, and paraphrased by others. To be *complete*, the definition must delineate the observable characteristics of the behavior. Therefore, it is recommended that, before deciding behavior recording procedures, the school psychologist should conduct a brief anecdotal observation to identify behavioral features, setting events, and so forth, and select a method of recording that will yield the most reliable and valid data.
